

The algebraic molecular model for ^{12}C and its application to the $\alpha+^{12}\text{C}$ scattering: from densities and transition densities to optical potentials, nuclear form factors and cross sections

Andrea Vitturi

Dipartimento di Fisica e Astronomia, and INFN, Padova

Recent advances on proton-neutron pairing, Saclay. September 2019

Motivations (1)

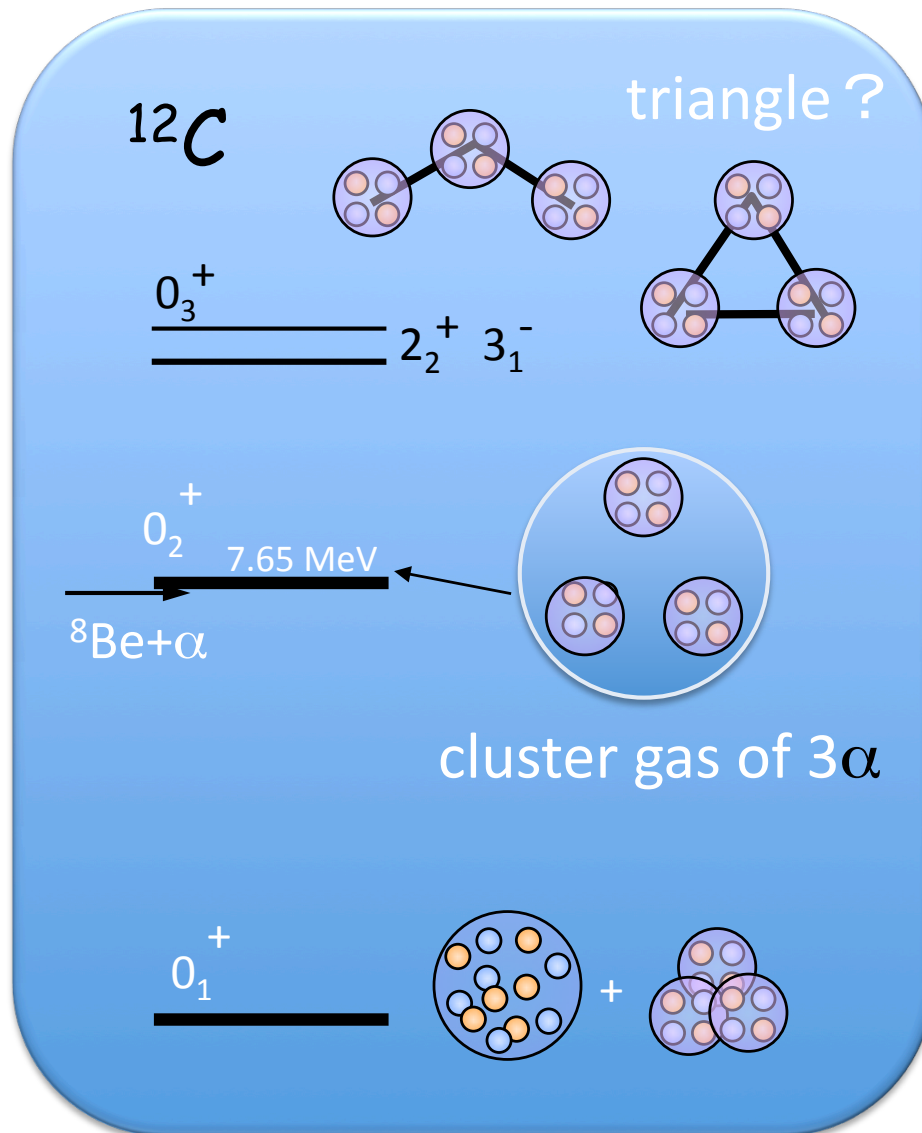

Evidence of alpha-clustering aspects in light nuclei
(e.g. ^{12}C)

Coexistence of cluster and non-cluster states in the
same nucleus

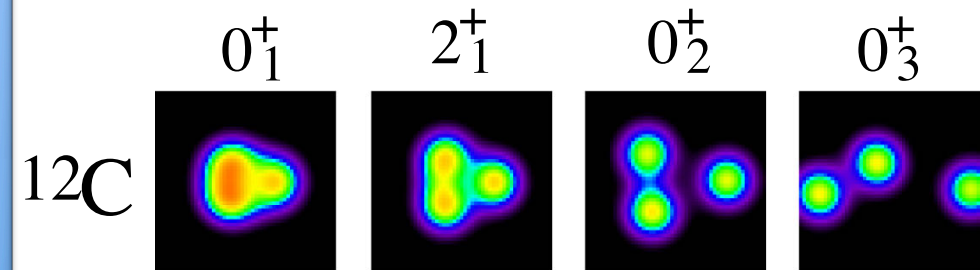

Emergence of cluster states from correlated nucleons
moving in the nuclear mean field or in *ab initio*
approaches

Two theoretical examples (technically rather complex):
AMD and large-scale Monte Carlo shell model

Antisymmetrized Molecular Dynamics

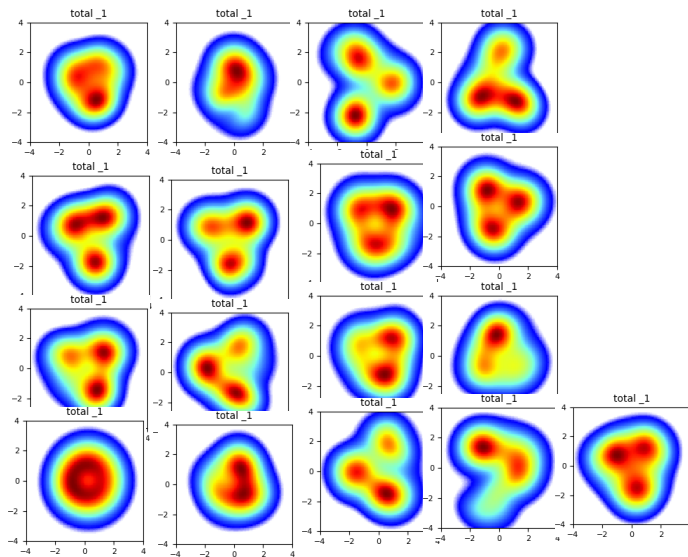

From Y. Kanada-En'yo
(and collaborators)

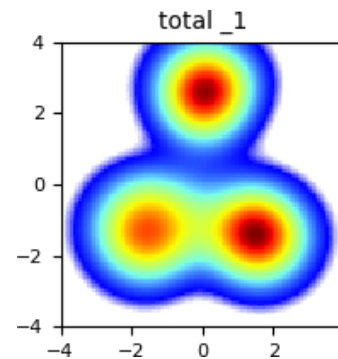

Monte Carlo Shell Model (Otsuka and the Tokyo group)

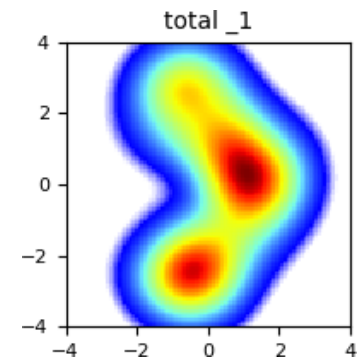

Procedure: calculation of "intrinsic" density from MCSM eigenstate

0^+_1 : mixture of many "shapes"

0^+_2 : main "shape"

0^+_3 : main "shape"

Motivations (2)

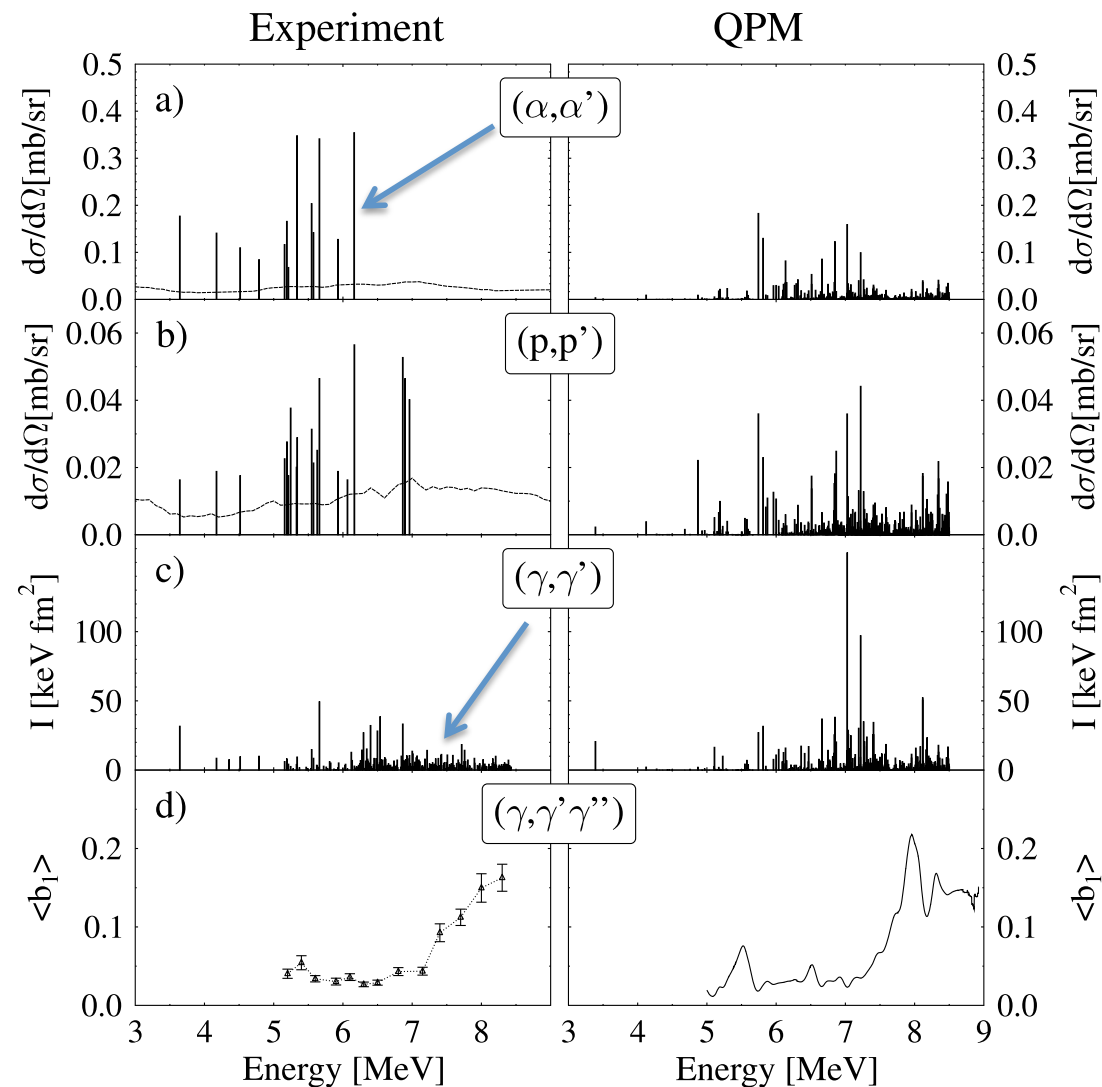

Need of combining different probes to study the different facets of a nuclear system
(Multi-messenger investigation)

In the specific case of ^{12}C in addition to information based on electromagnetic probes a special role is played by NUCLEAR inelastic excitation, as for example (α, α') scattering

Our approach: the algebraic cluster molecular model

Wheeler J A, 1937

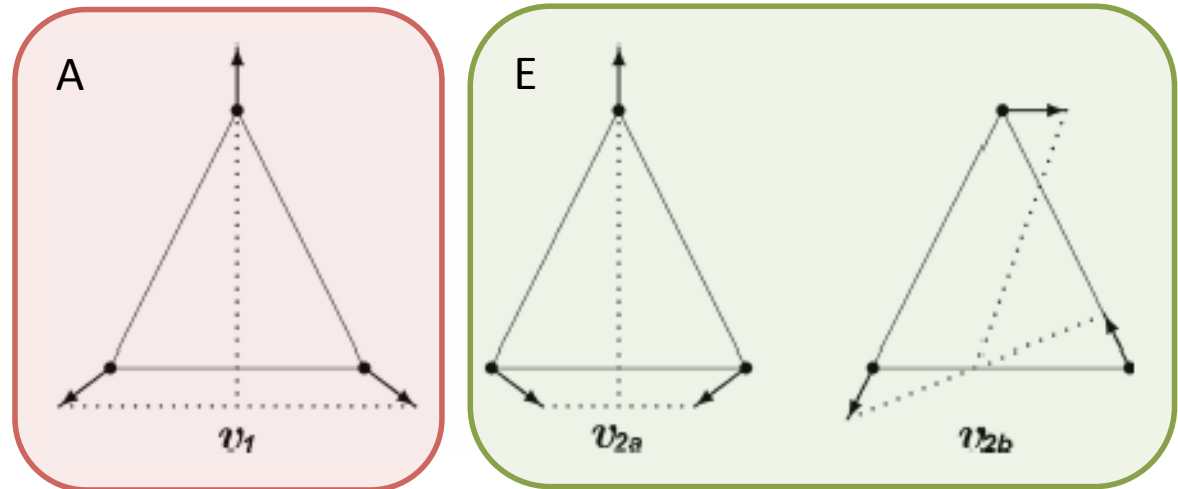

Iachello F, Bijker R. and collaborators, 2000

Three alpha-particles at
the vertices of a equilateral
triangle
(D_{3h} discrete symmetry)

Geometry of a three-body system.

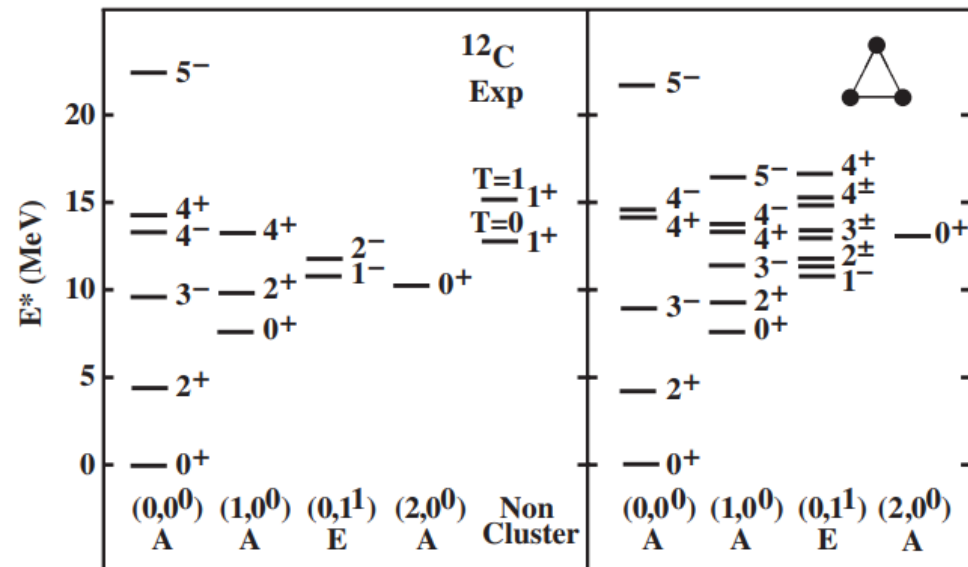

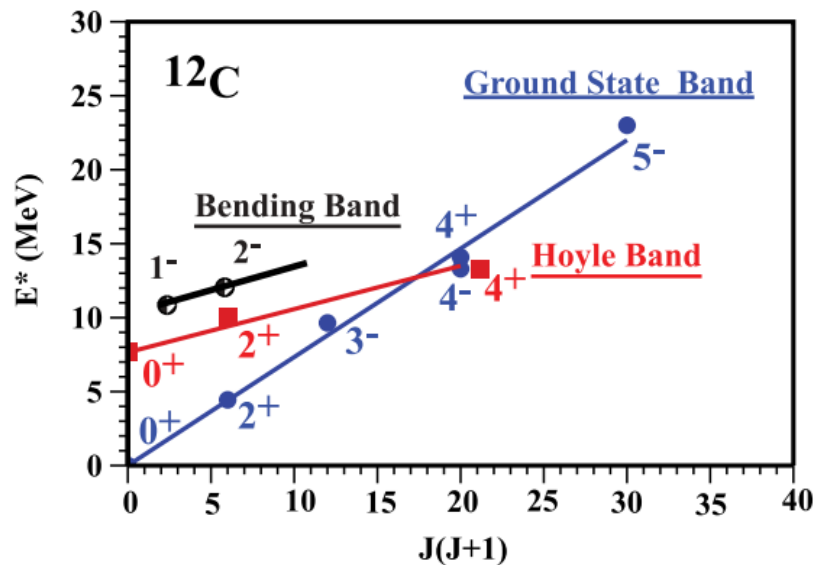

Intrinsic states are generated by the
normal modes of vibration of the triangle

Vibrations of an oblate top.

Each intrinsic state generates a rotational band, whose elements have allowed quantum numbers (angular momentum and parity) according to the rules of the point-group D_{3h}

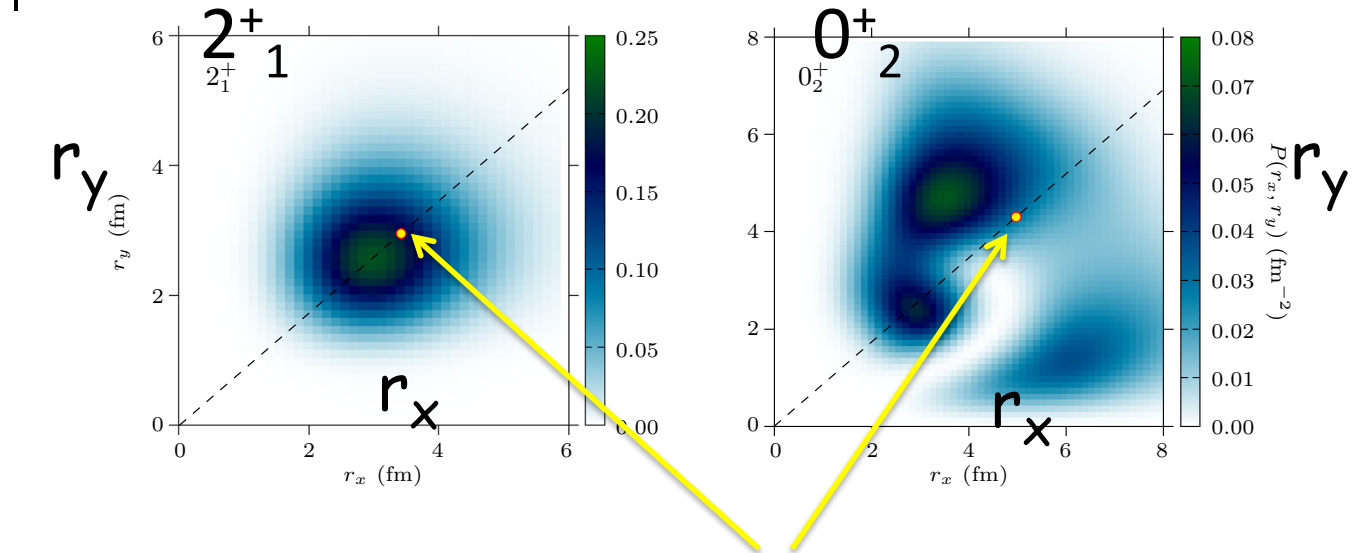

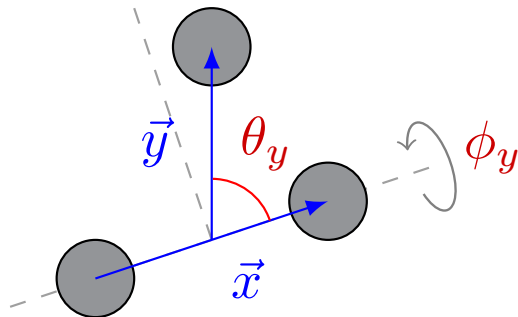

Evidence for triangular D_{3h} symmetry in ^{12}C
 [Marín-Lambarri PRL 113 (2014) 012502]

Further support to the basic triangular shape comes from our calculations based on the quantal solution of the problem of three interaction alpha's (via the two-body Ali-Bodmer plus a three-body potential) within the Hyperspherical Harmonics approach (HH), using for the continuum part pseudo-states given by Transformed Harmonic Oscillator (THO).

Results from the HH formulation support the description of the ground and 2^+_1 state of ^{12}C as three particles with the symmetry of an equilateral triangle. On the other hand the wave function for the Hoyle state seems to present a more complicated structure.

w.f. distributed around a mean triangular configuration

Casal, Fortunato,
Vitturi, 2019

The computed r_x , r_y r.m.s. values (yellow dots) are found to satisfy the equilateral ratio $r_y = r_x \sqrt{3}/2$ (dashed)

Densities and transition densities within the algebraic approach

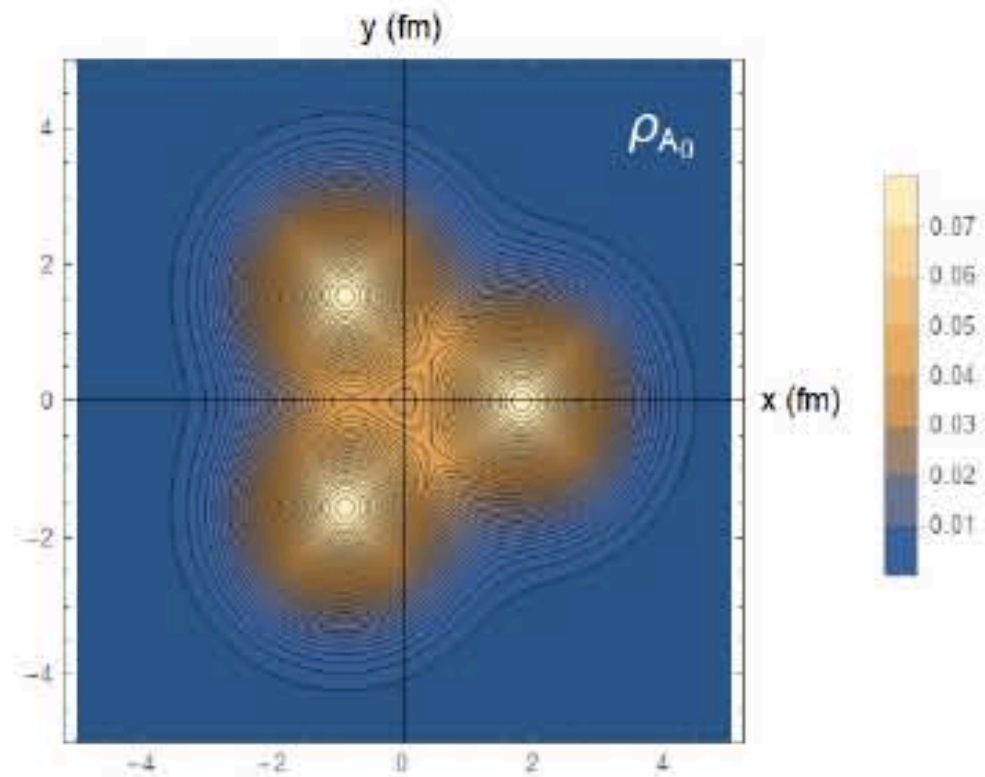

Gaussian density for an α :

$$\rho_{\alpha}(\vec{r}) = \left(\frac{d}{\pi}\right)^{3/2} e^{-d r^2}$$

$d = 0.56(2)$ to fit α radius

\Rightarrow "static" ^{12}C g.s. density:

$$\rho_{A_0}(\vec{r}, \{\vec{r}_k\}) = \sum_{k=1}^3 \rho_{\alpha}(\vec{r} - \vec{r}_k)$$

A_0 : fully symmetric representation of D_{3h} with 0 quanta of excitation

$\vec{r}_1 = (\beta, \pi/2, 0)$, $\vec{r}_2 = (\beta, \pi/2, 2\pi/3)$, $\vec{r}_3 = (\beta, \pi/2, 4\pi/3)$

Radial parameter β to reproduce some ^{12}C g.s. properties

Density expanded in spherical harmonics (ground-state band A_0)

$$\rho_{A_0}(\vec{r}) = \sum_{\lambda\mu} \rho_{A_0}^{\lambda\mu}(r) Y_{\lambda\mu}(\theta, \varphi)$$

Only multipoles allowed by D_{3h} :
 $\{00, 20, 33, \dots\}$

Radial transition densities

$\rho_{A_0}^{00}(r)$ intrinsic 0_1^+ g.s. density

$\rho_{A_0}^{20}(r)$ associated to 2_1^+

...

$\beta = 1.82 \text{ fm} \Rightarrow$ reproduce the g.s. radius and the $B(E2)$ value to the 2_1^+

$$\sqrt{\langle r^2 \rangle_{0_1^+}} = \frac{\sqrt{4\pi}}{3} \int r^4 \rho_{A_0}^{00}(r) dr, \quad M(E\lambda; \lambda \rightarrow 0_1^+) = Z \int r^{2+\lambda} \rho_{A_0}^{\lambda}(r) dr$$

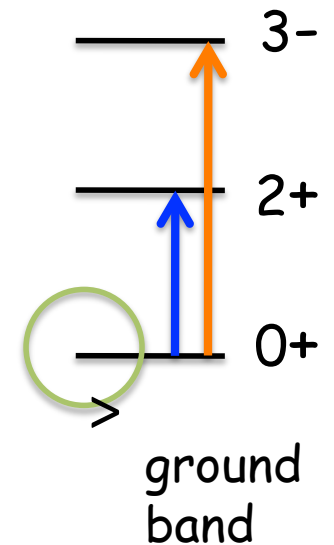

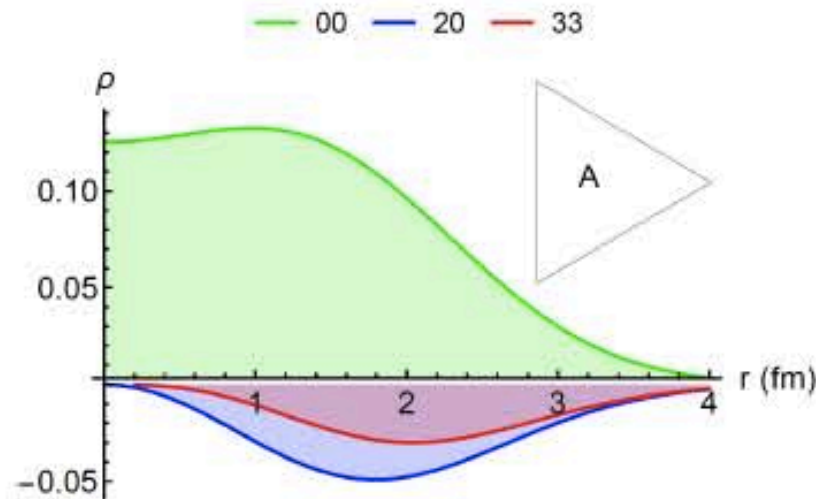

TABLE I: Calculated observables within the g.s. band.

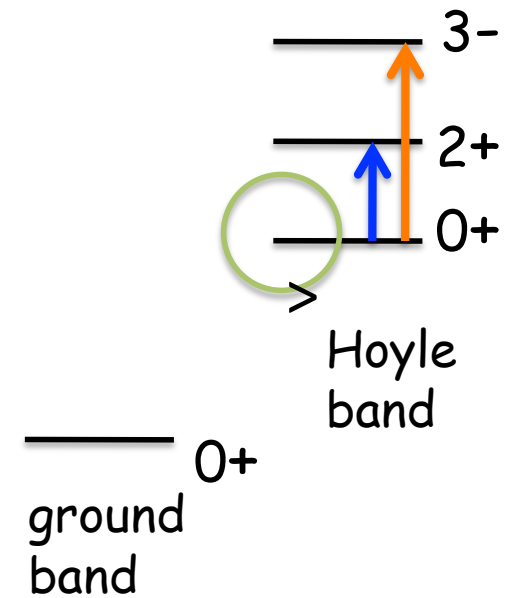

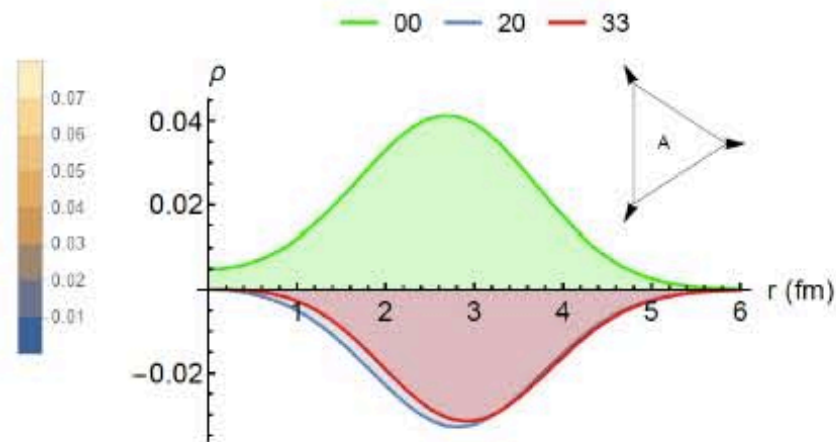

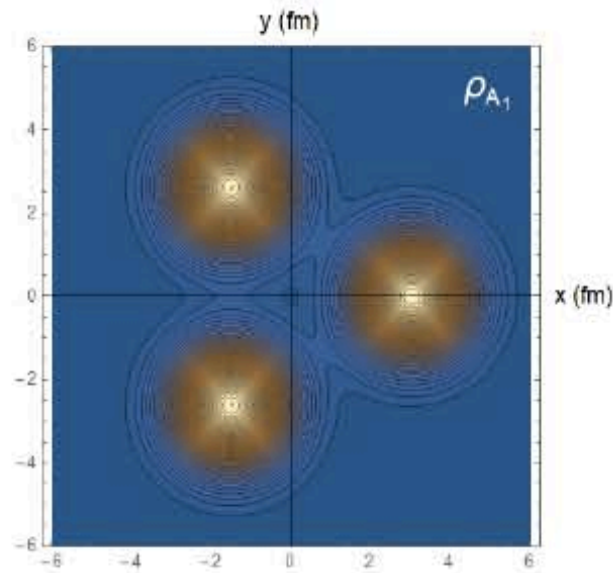

$\langle r^2 \rangle_{0_1^+}^{1/2}$	2.45 (fm)
$B(E2; 2_1^+ \rightarrow 0_1^+)$	7.86 (e ² fm ⁴)
$B(E3; 3_1^- \rightarrow 0_1^+)$	65.07 (e ² fm ⁶)
$B(E4; 4_1^+ \rightarrow 0_1^+)$	96.99 (e ² fm ⁸)

	exp		AMD		AMD+GCM		RGM	
	$B(E\lambda)$	(error)	$B(E\lambda)$	f_{tr}	$B(E\lambda)$	f_{tr}	$B(E\lambda)$	f_{tr}
$E2 : 2_1^+ \rightarrow 0_1^+$	7.59	(0.42)	8.53	0.94	9.09	0.91	9.31	0.90
$E0 : 0_2^+ \rightarrow 0_1^+$	29.2	(0.2)	43.5	0.82	43.3	0.82	43.8	0.82
$E2 : 0_2^+ \rightarrow 2_1^+$	13.5	(1.4)	25.1	0.73	24.1	0.75	5.6	1.56
$E2 : 2_2^+ \rightarrow 0_1^+$	1.57 ^a	(0.13)	0.39	1.99	0.49	1.93	2.48	0.80
$E2 : 3_1^- \rightarrow 1_1^-$			40.7	1	79.0	1		
$E0 : 0_3^+ \rightarrow 0_1^+$			5.2	1	10.0	1		
$IS1 : 1_1^- \rightarrow 0_1^+$			2.6	1.57 ^b	2.4	1.93 ^b	5.7	1
$IS1 : 1_2^- \rightarrow 0_1^+$					1.5	1		
$E3 : 3_1^- \rightarrow 0_1^+$	103	(17)	71	1.20	71	1.20	125	0.91
$E4 : 4_1^+ \rightarrow 0_1^+$			733	1	995	1	655	1
$E3 : 3_1^- \rightarrow 0_2^+$			428	1	1210	1	228	1
$E2 : 2_2^+ \rightarrow 0_2^+$			102	1	182	1	212	1
$E2 : 2_2^+ \rightarrow 0_3^+$			309	1	223	1		

A-type vibration with $n = 1$ (Hoyle-state band, A_1)

Symmetric displacements $\Delta\beta^A$; "breathing mode"

$\Delta\beta^A = 1.2 \text{ fm} \Rightarrow \sim 1 \text{ fm increase in radius}$
(consistent with e.g. Ito [PRC 97 (2018) 044608] and others)

Transition densities connecting the g.s. and Hoyle bands ($A_0 \rightarrow A_1$)

Expansion in small displacements $\Delta\beta$, kept at leading order:

$$\delta\rho_{A_0 \rightarrow A_1}(\vec{r}) \simeq \chi_1 \frac{d}{d\beta} \rho_{A_0}(\vec{r}, \beta) = \sum_{\lambda\mu} \delta\rho_{A_0 \rightarrow A_1}^{\lambda\mu}(r) Y_{\lambda\mu}(\theta, \varphi)$$

χ_1 adjusted to reproduce $E0$ strength

Interband radial transition densities

$\delta\rho^{00}(r)$ monopole transition 0_1^+ g.s. \rightarrow 0_2^+ Hoyle

$\delta\rho^{20}(r)$ quadrupole transition 0_1^+ g.s. \rightarrow 2_2^+

...

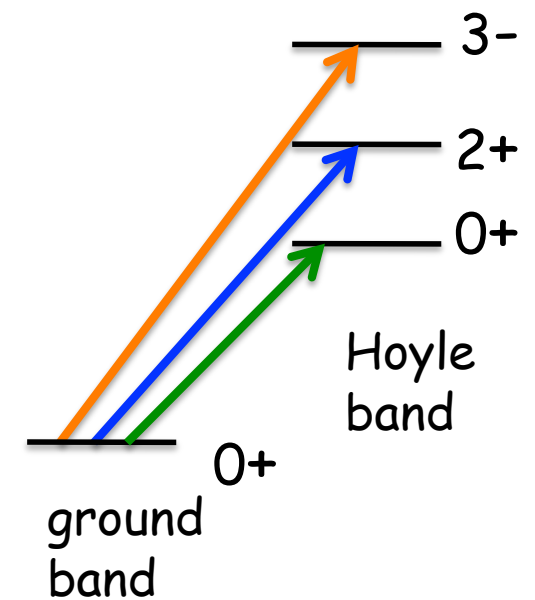

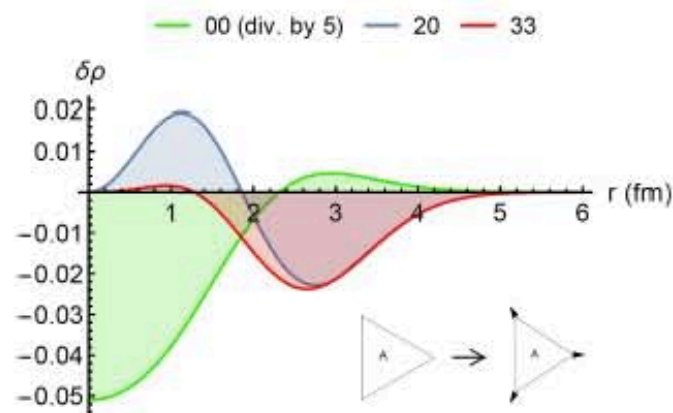

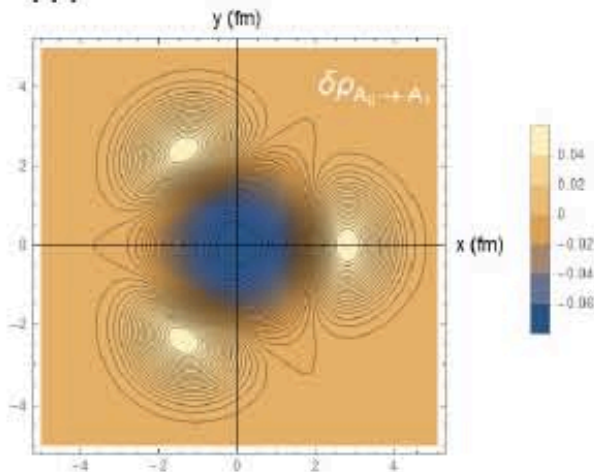

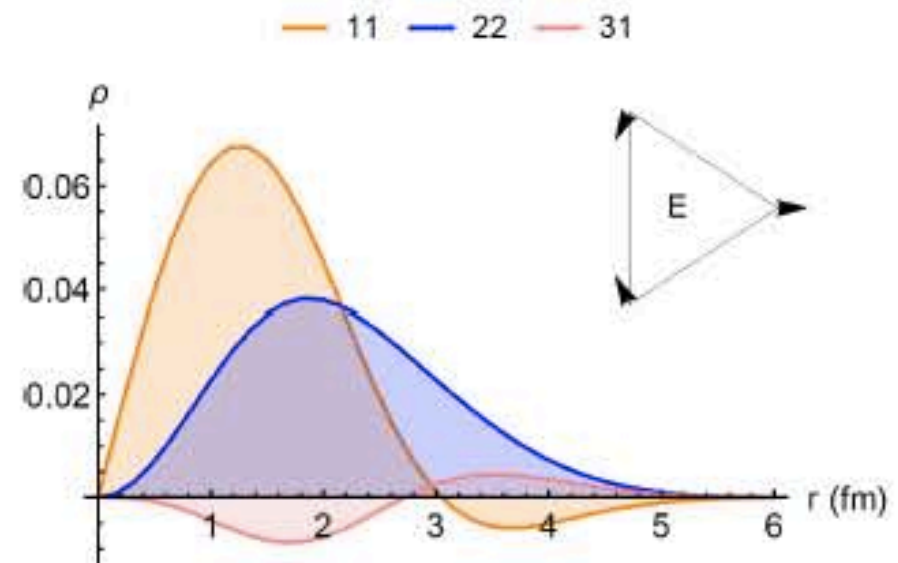

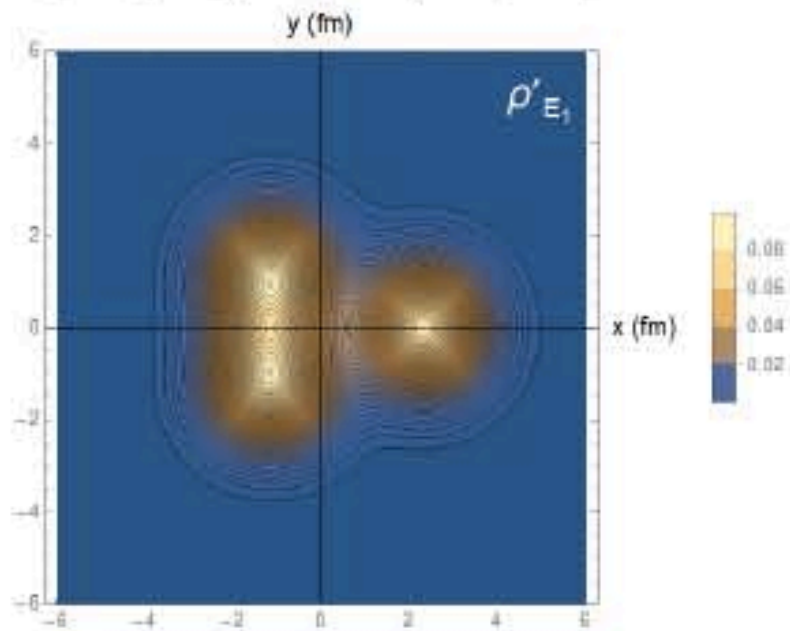

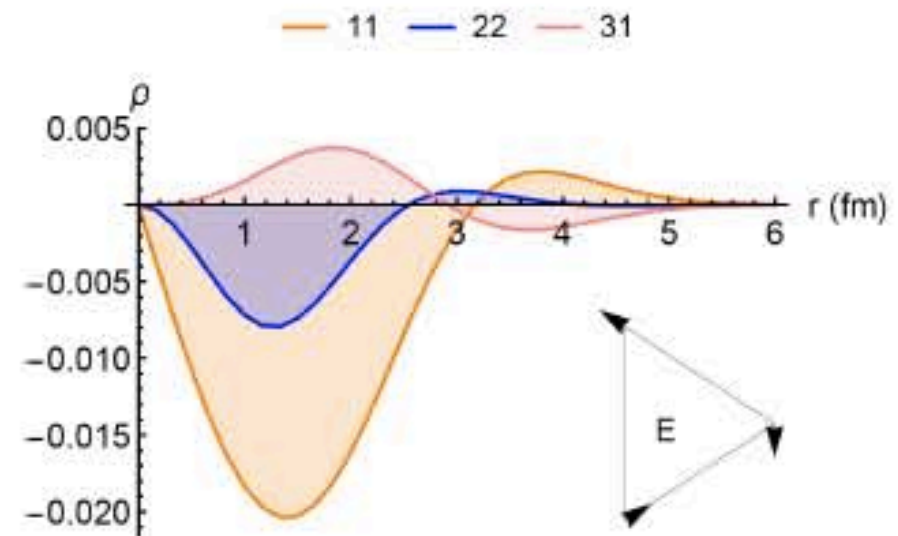

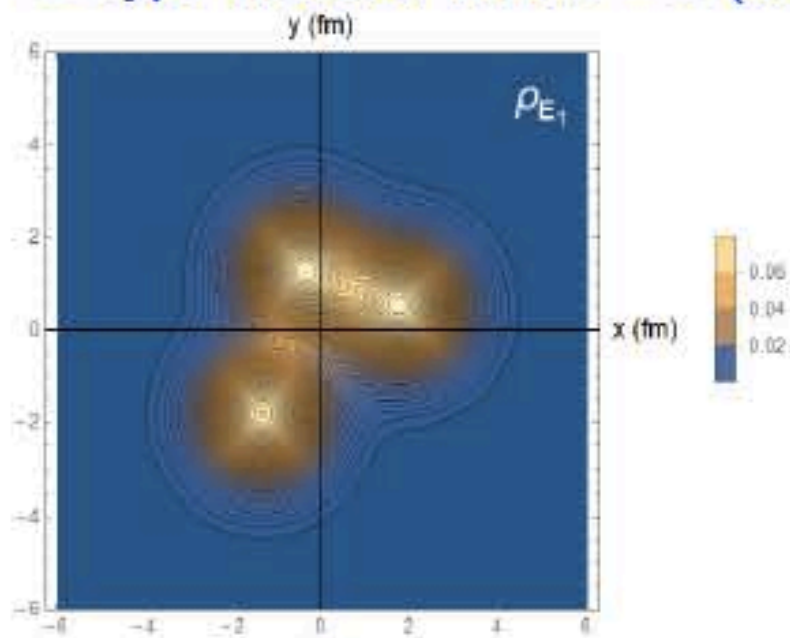

TABLE II: Quantities calculated in the present work for the Hoyle band, using the values of β , χ_1 given in the text.

	$\langle r^2 \rangle_{0_2^+}^{1/2}$		3.44 (fm)	
	$B(E2; 2_2^+ \rightarrow 0_1^+)$		0.58 (e ² fm ⁴)	
	$B(E2; 0_2^+ \rightarrow 2_1^+)$		2.90 (e ² fm ⁴)	
	$B(E3; 3_2^- \rightarrow 0_1^+)$		70.42 (e ² fm ⁶)	
	$M(E0; 0_2^+ \rightarrow 0_1^+)$		5.4 (e fm ²)	

	exp		AMD		AMD+GCM		RGM	
	$B(E\lambda)$	(error)	$B(E\lambda)$	f_{tr}	$B(E\lambda)$	f_{tr}	$B(E\lambda)$	f_{tr}

E -type vibration with $n = 1$ (doubly degenerate E_1)

Transition densities $A_0 \rightarrow E_1$

From densities and transition densities to potentials and form factors

alpha+¹²C: folding densities and transition densities with the density of the projectile alpha

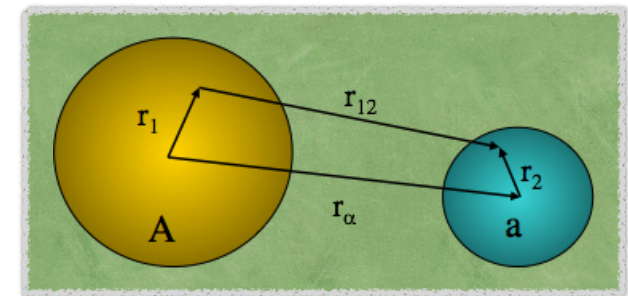

Form factors $F_{ij}(R)$, using:

- Transition densities within the algebraic cluster model

$$F_{ij}(R) = \int \int \rho_\alpha(\vec{r}_1 - \vec{R}) v_{NN}(|\vec{r}_{12}|) \delta \rho^{i \rightarrow j}(\vec{r}_2) d\vec{r}_1 d\vec{r}_2$$

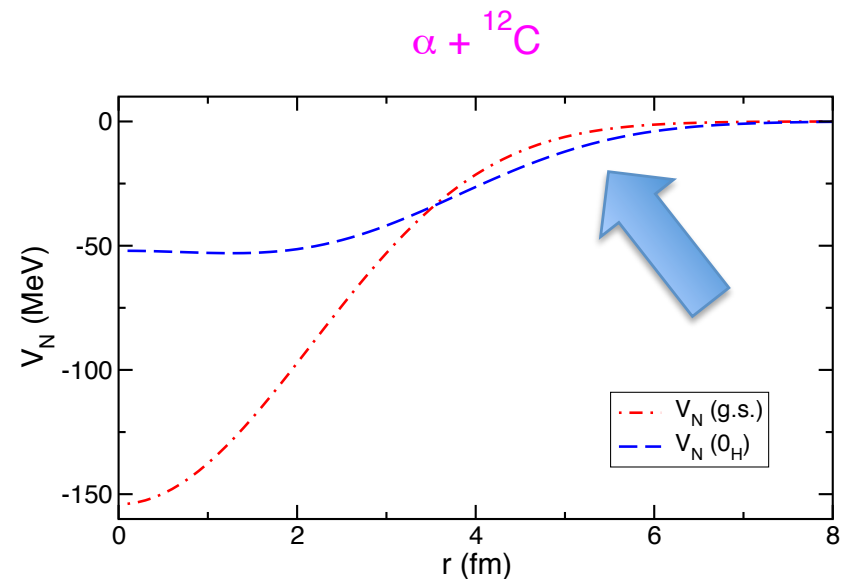

(v_{NN} : Reid-type M3Y)

Double folding procedure

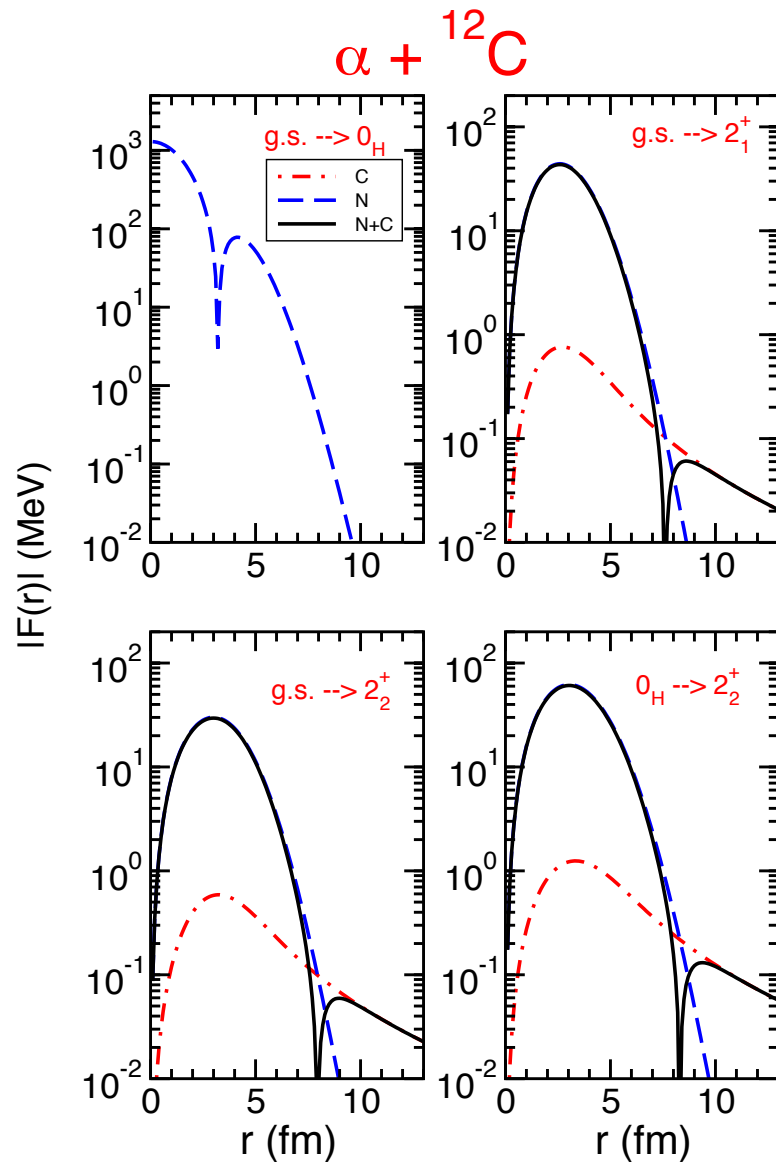

Diagonal terms: potentials

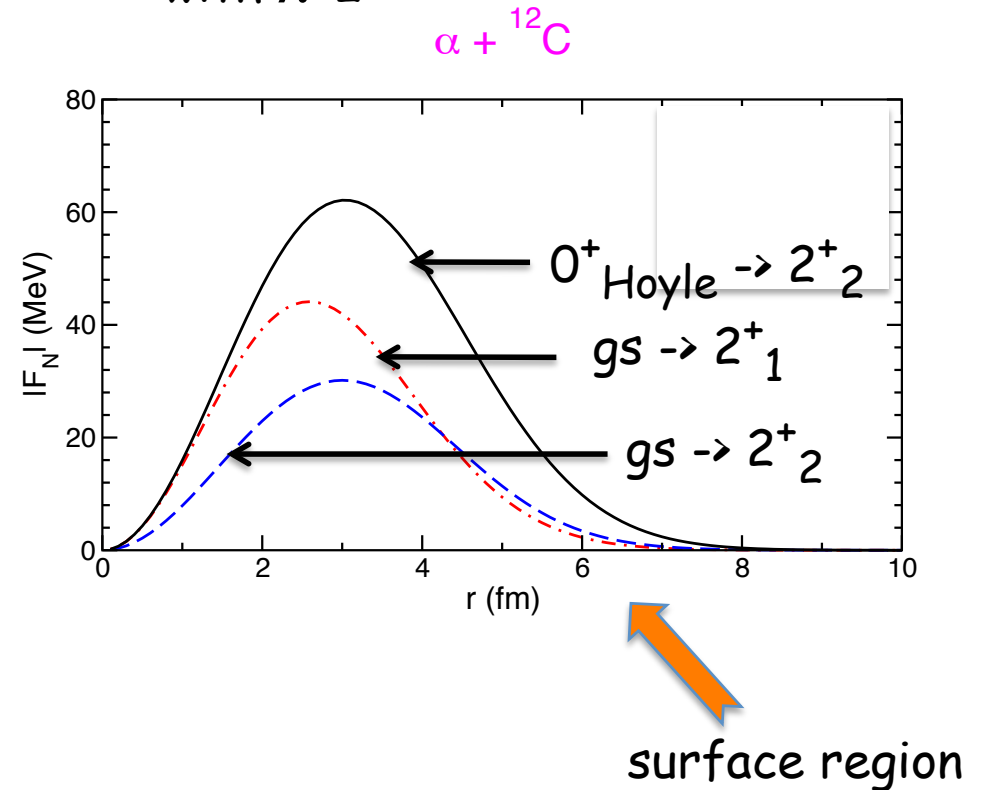

Potentials are different within the different bands

Formfactors (including nuclear and coulomb contributions)

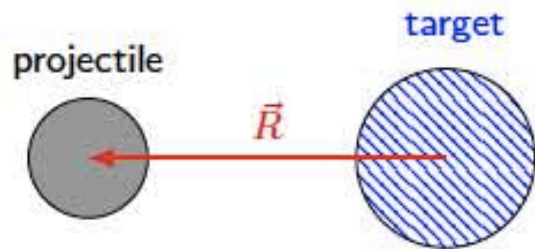

Nuclear part of the form factors
with $\lambda=2$

From potentials and form factors to cross sections

Coupled-channels calculations: $\alpha + {}^{12}\text{C}$ inelastic scattering

$$c \equiv \{L(nj)\}, \quad J = L + j$$

$$\Psi_c^{JM}(\xi, R) = \sum_{c'} \frac{i^L}{R} \chi_{c,c'}^J(R) \Phi_{c'}^{JM}(\hat{R}, \xi)$$

$$\Phi_c^{JM}(\hat{R}, \xi) = \left[Y_L(\hat{R}) \otimes \phi_{nj}(\xi) \right]_{JM}$$

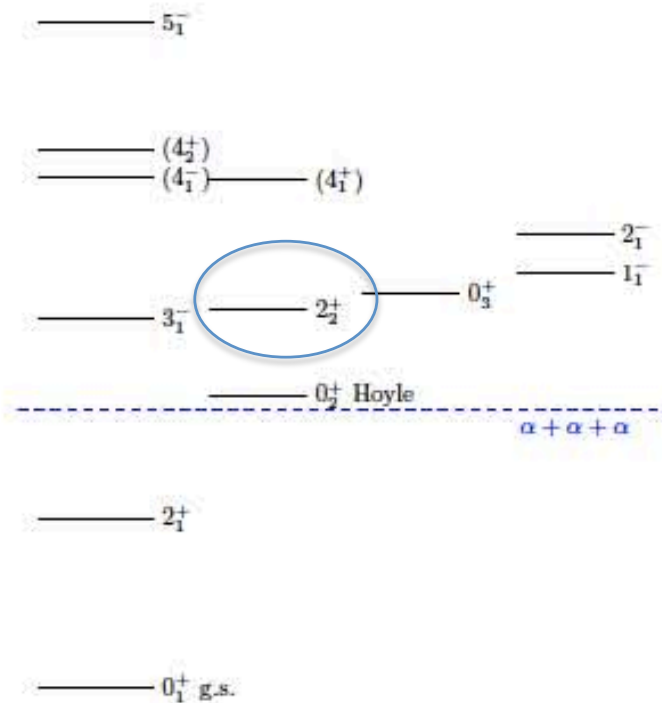

$$\left[-\frac{\hbar}{2m_r} \left(\frac{d^2}{dR^2} - \frac{L(L+1)}{R^2} \right) + E_{nj} - E \right] \chi_{c,c}^J(R) + \sum_{c'} i^{L'-L} V_{c,c'}^{JM}(R) \chi_{c,c'}^J(R) = 0$$

Requires $V_{c,c'}^{JM}(R) = \langle \Phi_c^{JM} | \hat{U}_{pt} | \Phi_{c'}^{JM} \rangle$ coupling potentials;
can be written in terms of **form factors** $F_{n'j',nj}(R)$

α inelastic scattering on ^{12}C

- Population of cluster states
- Study of isoscalar monopole and dipole excitations

our model
space

E.g.:

2_2^+ state measured at 9.84 MeV
[Itoh PRC84(2011)054308]

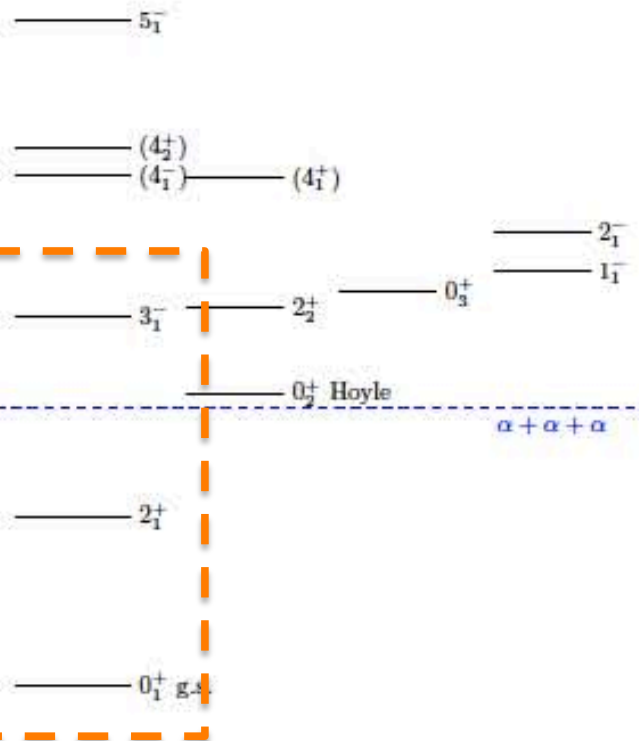

5_1^- state measured at 22.4 MeV
[Marín-Lambarri PRL113(2014)012502]

Many theoretical coupled-channel (CC) calculations using different (microscopic) structure models for ^{12}C :
AMD [Kanada-En'yo], FMD [Neff, Feldmeier], RGM [Kamimura, Ogata], ...

This work: Assess whether the algebraic model describes exp. data
Compare results with those from the HH framework

α inelastic scattering on ^{12}C

- Population of cluster states
- Study of isoscalar monopole and dipole excitations

our model
space

first trial case

E.g.:

2_2^+ state measured at 9.84 MeV
[Itoh PRC84(2011)054308]

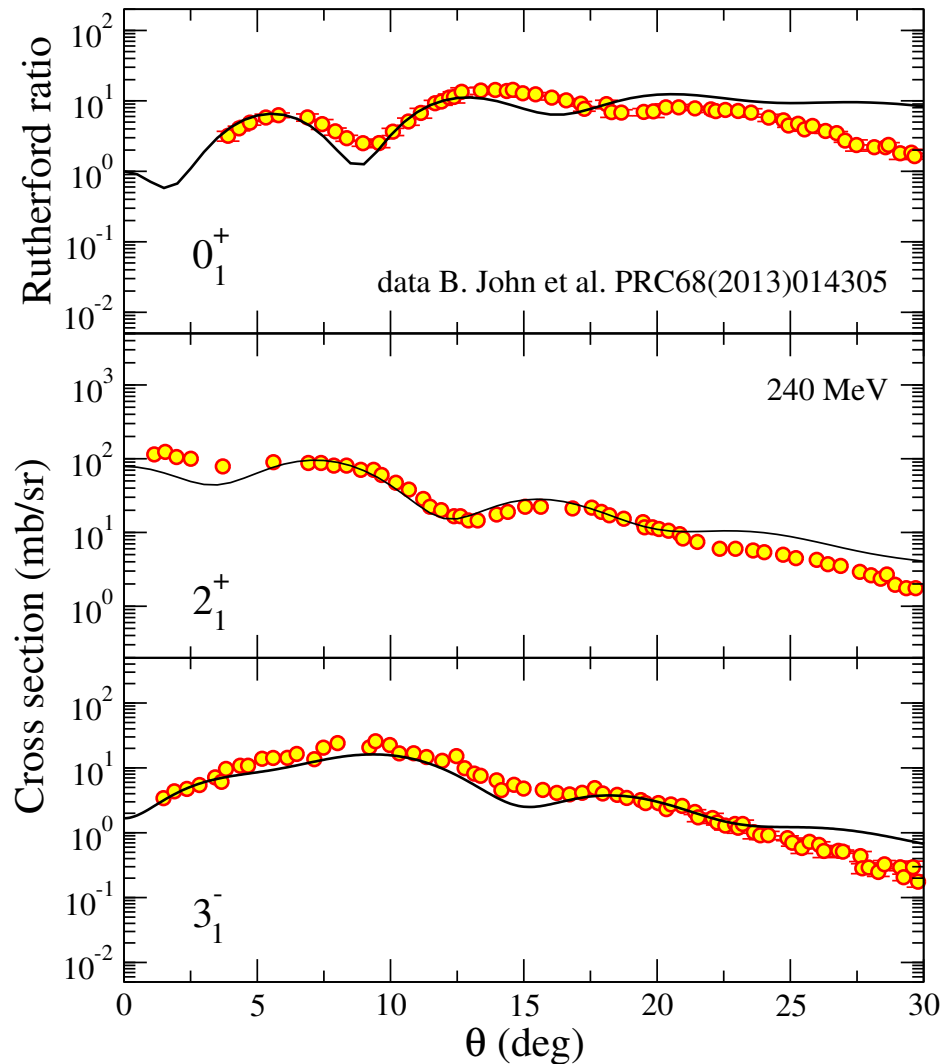

5_1^- state measured at 22.4 MeV
[Marín-Lambarri PRL113(2014)012502]
