## Un nouvel accélérateur linéaire à électrons a été inauguré à Saclay par le ministre de la recherche

M. Galley, minisire de la recherche et des questions atomiques et spatiales, a inauguré mercredi un accélérateur de particules construit par le CEA, dans une annexe du contre d'éludés nucléaires de Saclay, l'Orme-des-Merisiers. Celle nouvelle machine, que l'on désigne sous le nom d'A.L.S. (Accélérateur linéaire de Saclay), doit permettre de conférer à des électrons une énergie de 600 millions d'électrons-volts (MeV) ; il permet des études nouvelles sur la

?

Christophe Tzara  
(1927-2018)  
ALS lead scientist  
Chef de service  
Physics “guru” until  
~1987

# ALS: Accélérateur Linéaire (d'électrons) de Saclay

## ◆ Main linac characteristics

- Length: 200 m
- Energy: 150 to 700 MeV
- Duty cycle: 1-2% (compare to  $10^{-3}$  or  $10^{-4}$  for older machines)
- Pulse length: 10  $\mu$ s
- Rate: 1000 or 2000 p/s
- Peak current: 60 mA
- Mean current: up to 100  $\mu$ A

## ◆ Detection systems

- + High resolution:  $\sim 10^{-4}$
- + Lowest possible background

Albert Messiah  
(1921-2013)  
CEA director of  
DPbN: 1965-1972  
Physics: 1972-1982

talk at HEP Conference Columbia U., (USA) 1969:

...

*§to be able to perform precision experiments with real or virtual photons of energy-momentum ranging from 100 to 500 MeV or more. This leads one to energies ranging up to 500 MeV, say, for the primary electron beam, together with order of magnitude improvements in the other beam characteristics, notably in intensity and duty cycle.*

# Accelerator tunnel

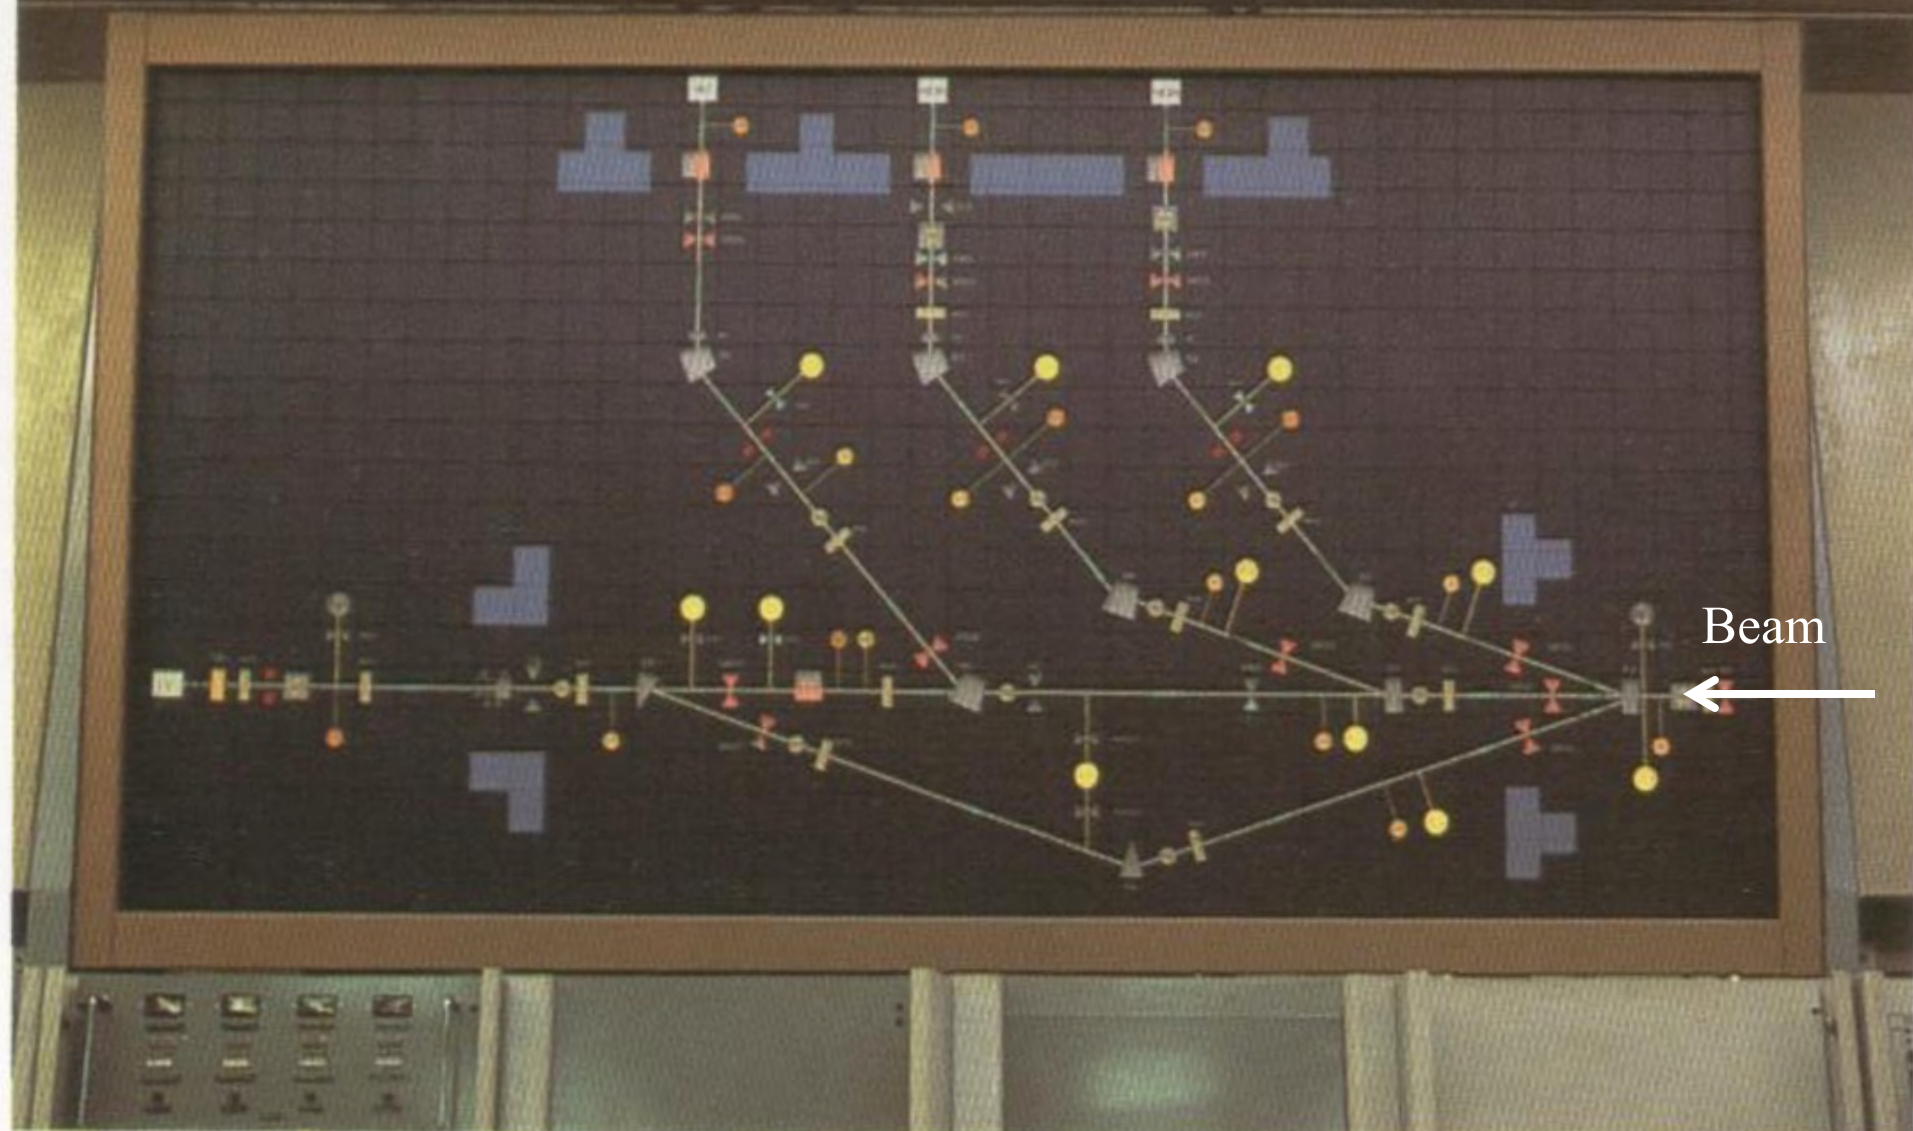

## Main Control room

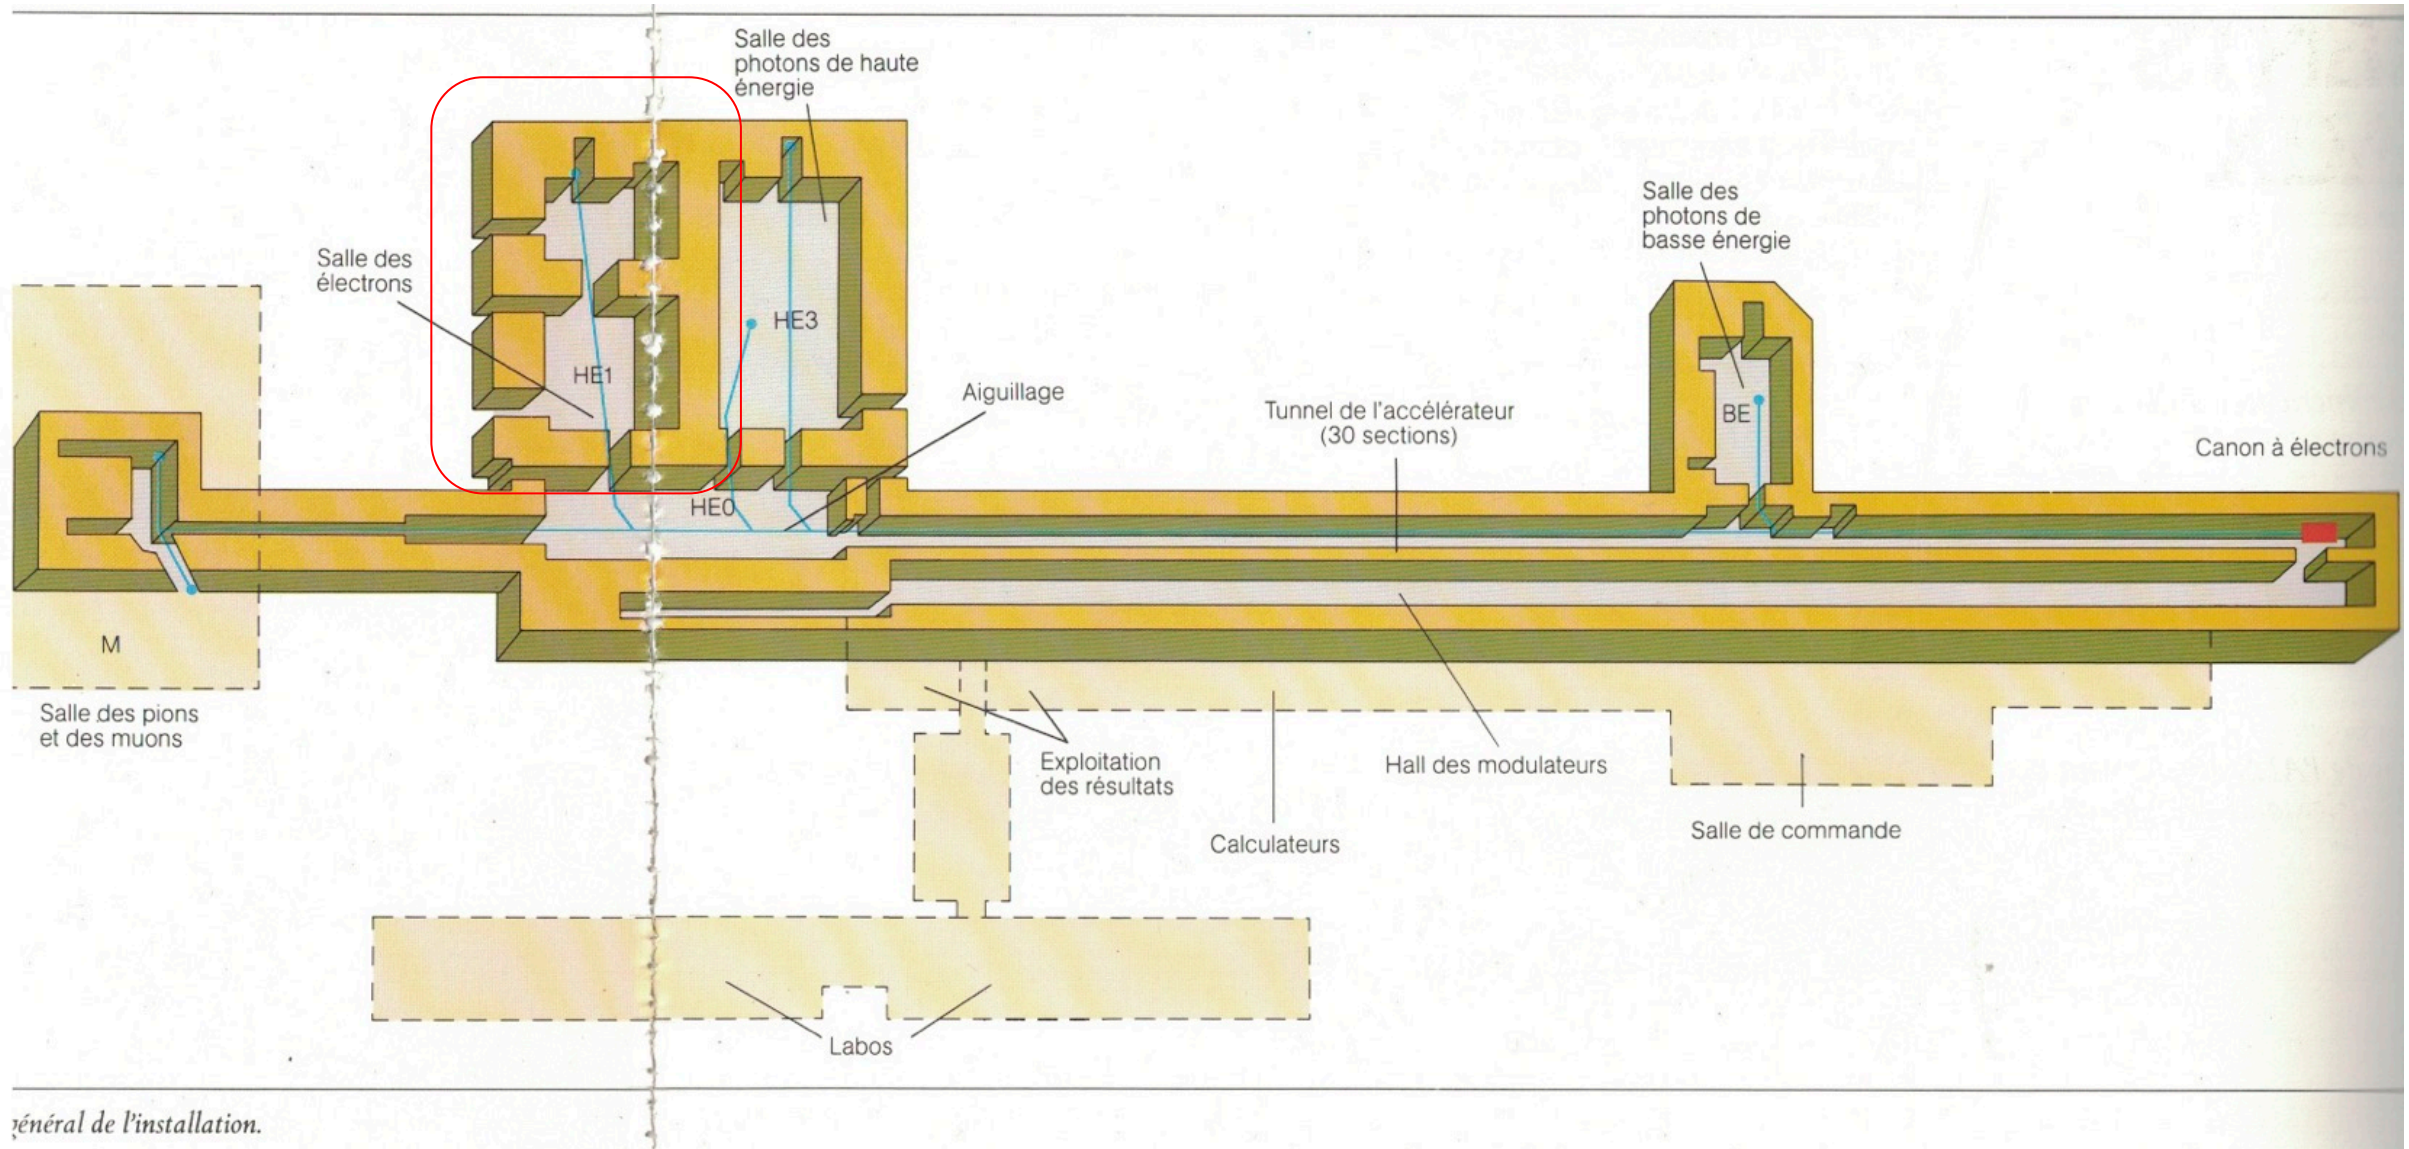

## Beam switchyard panel

# Simplified view of the laboratory (top view)

# Electron scattering

## ◆ Main advantages:

- EM interaction is weak ( $\alpha = 1/137$ )
- EM interaction is known (QED)
- One photon exchange is a **very good** approximation
- Vary the 3-transfer  $q$  and the energy  $\omega$  independently
- Vary the polarization of the virtual photon

+ ...

$$= q_\mu^2 = 4ee' \sin^2(\theta/2); \quad q_\mu = (\omega, q); \quad \omega = e - e'$$

## ◆ Distance scale : nucleus is probed with a wavelength $\lambda \sim 1/q$

- for  $q$  values of about  $2\text{-}3 \text{ fm}^{-1}$  ( $\sim 0.5 \text{ GeV}/c$ ) probe distances smaller than  $1 \text{ fm}$ .

(nuclear physics: from  $5\text{-}6 \text{ fm}$  to  $0.1 \text{ fm}$ )

A microscope to probe the spatial structure of nuclei

# Elastic electron scattering: basic reminders

- ◆ Point nucleus with charge  $Z$ , no spin (Mott, 1932):

$$\sigma_{Mott}(\theta) = \left( \frac{Ze^2}{2E} \right)^2 \frac{\cos^2(\theta/2)}{\sin^2(\theta/2)}$$

1977  
sir N.F. Mott (1905-1996)

- ◆ Finite size nucleus

$$\sigma_0 = \sigma_{Mott}(\theta) \cdot F_{ch}^2(q)$$

- ◆ Form factor  $F_{ch}(q)$ : ( $r$  = radius)

$$F_{ch}(q) \propto \int_0^\infty \rho(r) \frac{\sin(qr)}{qr} r^2 dr$$

Possible models for  $\rho_{ch}(r)$  (Hoftsadter, 1956)

The charge form factor is a Fourier transform of the nuclear charge distribution

# Nuclear charge distributions

## ◆ Cross section for (e,e') on $^{208}\text{Pb}$

Precise determination of the charge density down to  $r = 0$  fm

## Charge density

Frois et al., PRL 38, 152 (1977)

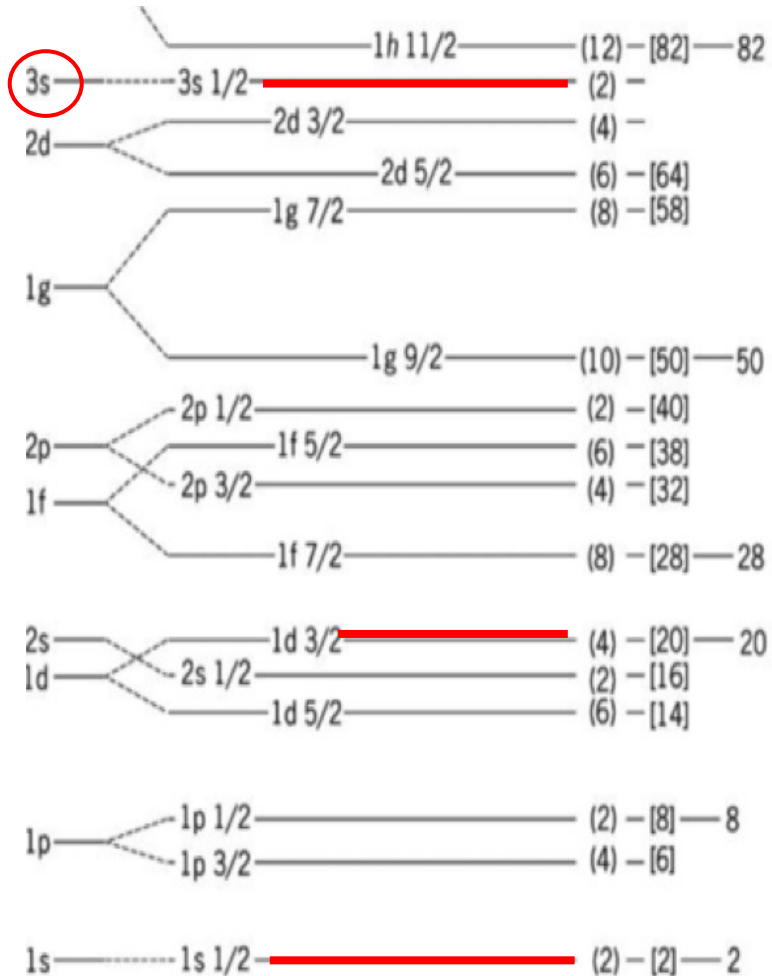

## Error estimates vs $q$ ( $\text{fm}^{-1}$ )

# Where is the difference coming from?

## ◆ Nuclear shell model near $^{208}\text{Pb}$

## Predicted 1s, 2s and 3s charge densities

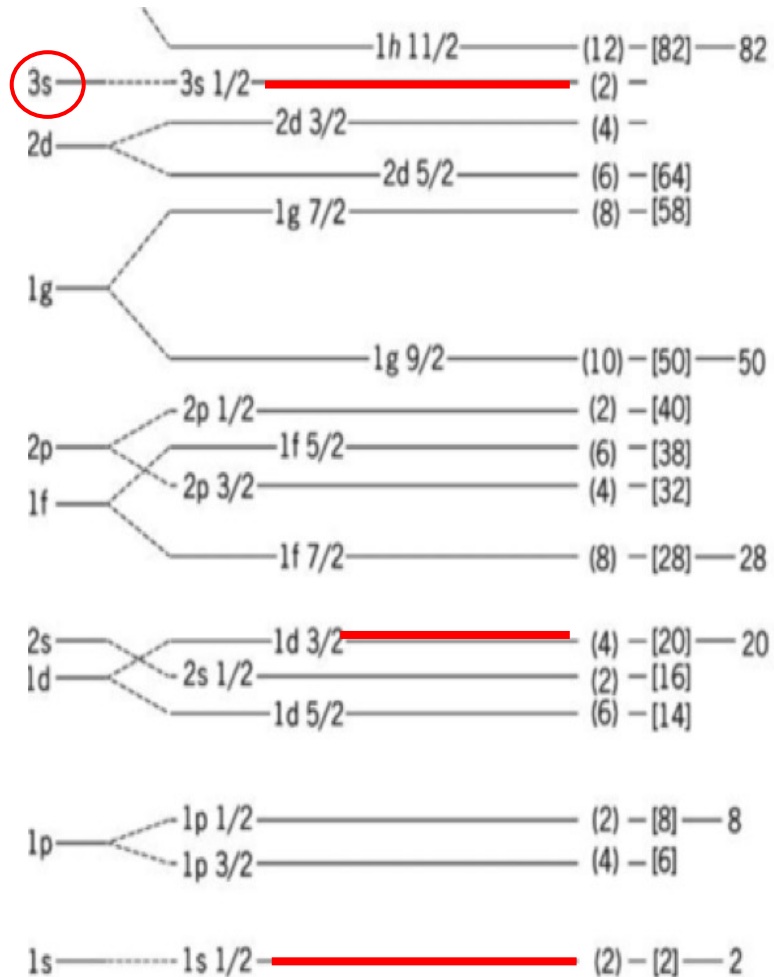

Should we trust the shell model in the nuclear interior?  
 => Need a measurement of the most inner, 3s, orbit

# Isolate the 3s proton orbit

- ◆ Charge densities of  $^{206}\text{Pb}$  and  $^{205}\text{Tl}$ : differ by one 3s proton

Cavedon et al.,  
PRL 49, 978 (1982)

Predicted  $^{205}\text{Tl}/^{206}\text{Pb}$  cross  
section ratio (DDHF)

The 3s difference in  $\rho(r)$  results in a large peak around  $q = 2 \text{ fm}^{-1}$

# What about the 3s proton orbit?

Experimental  $^{205}\text{Tl}/^{206}\text{Pb}$   
cross section ratio (DDHF)

Density differences

Cavedon et al.,  
PRL 49, 978 (1982)

3s = 100%

3s = 70%

- 1/ Shell model concept is valid in the nuclear interior
- 2/ Shape of the 3s orbit is well described in DDHF(B).
- 3/ Configuration mixing is about 30%

# Charge density distributions for doubly-closed shell nuclei

Frois and Papanicolas,  
ARNPS 37, 133 (1987)

Figure 8 Charge density distributions of doubly closed-shell nuclei. The thickness of the solid line depicts the experimental uncertainty. The mean field calculations are from (53).

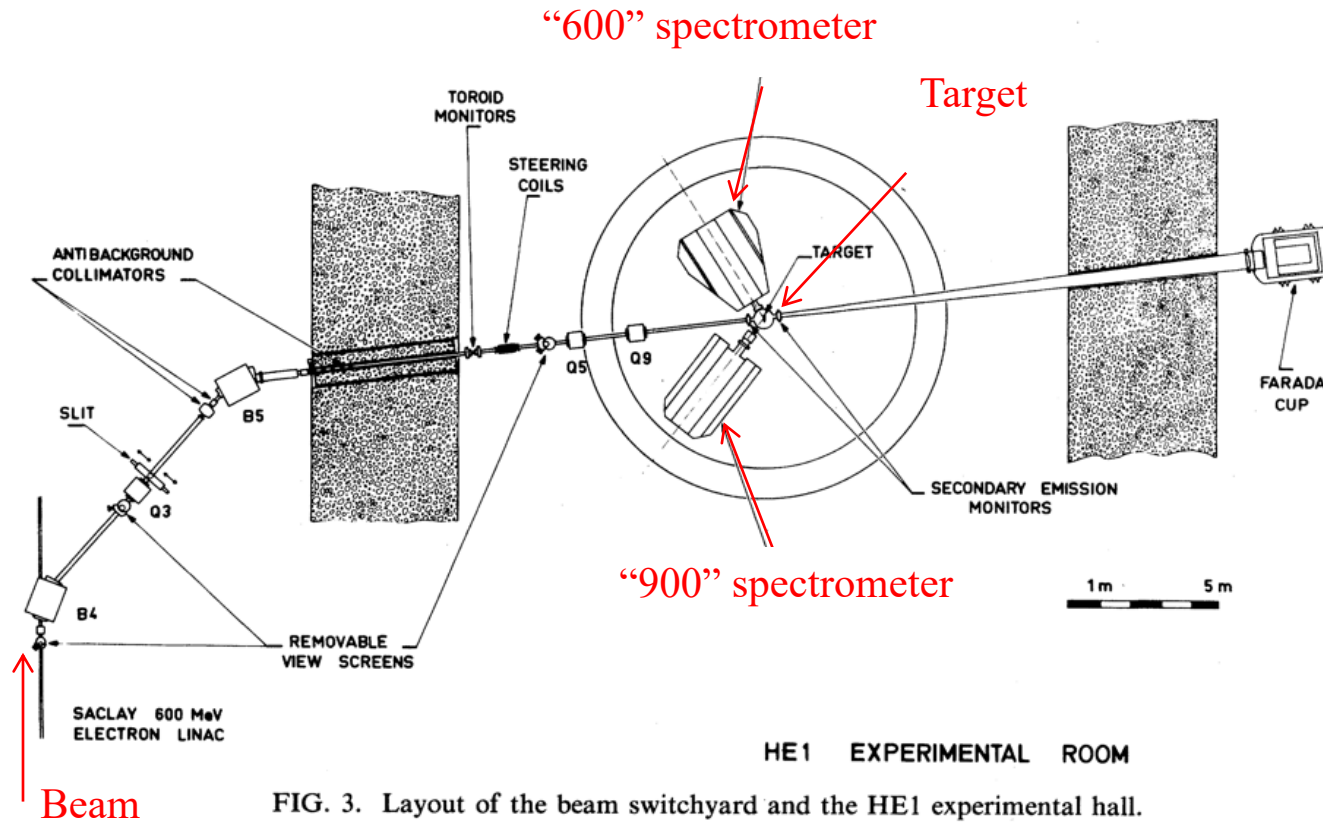

Overall good agreement between mean-field theory and data  
No specific trend as a function of A

# ALS: HE1 experimental hall: $(e,e')$ and $(e,e'p)$

P. Leconte et al.,  
NIM 169, 401 (1980)

## TOP VIEW

The fathers of the HE1 experimental hall

Philippe Leconte

Jean Mougey

# Detector casemate

Example  
for  $^{208}\text{Pb}$ :

36 hours  
without a  
single  
count in  
the elastic  
peak  
region

Excellent shielding: mandatory for low cross-section measurements

# Electron scattering: a spin $J_0$ nucleus

## ◆ General case (elastic or inelastic)

$$\frac{d\sigma}{d\Omega dE} = \frac{4\pi}{M} \sigma_{Mott} \eta^{-1} \left[ \frac{q_\mu^2}{q^2} S_L(q, \omega) + \left( \frac{1}{2} \frac{q_\mu^2}{q^2} + \tan^2 \frac{\theta}{2} \right) \frac{q_\mu^2}{q^2} S_T(q, \omega) \right]$$

Donnelly and Walecka,  
ARNPS, 329 (1975)

## ◆ For elastic scattering : ( $\omega=0$ )

$$\frac{d\sigma}{d\Omega}(q) = \sigma_{Mott} \eta^{-1} \left[ F_L^2(q) + \left( \frac{1}{2} + \tan^2 \frac{\theta}{2} \right) F_T^2(q) \right]$$

$$F_L^2(q) = \sum_{J=0}^{2J_0} F_{CJ}^2(q) = \frac{4\pi}{2J_0 + 1} \sum_{\text{even } J} \left| \langle \psi_A \| M_J^{Coul}(q) \| \psi_A \rangle \right|^2$$

$$F_T^2(q) = \sum_{J=0}^{2J_0} F_{MJ}^2(q) = \frac{4\pi}{2J_0 + 1} \sum_{J=0}^{2J_0} \left| \langle \psi_A \| \hat{T}_J^M(q) \| \psi_A \rangle \right|^2$$

# Radial extension of an individual nucleon orbit?

## ◆ Magnetic (on the magnetization distribution) electron scattering

Donnelly and Walecka,  
Nucl. Phys. A201, 81 (1973).

- On  $J_0 \neq 0$  nuclei

$$\frac{d\sigma}{d\Omega}(q) = \sigma_{Mott} \eta^{-1} \left[ F_L^2(q) + \left( \frac{1}{2} + \tan^2 \frac{\theta}{2} \right) F_T^2(q) \right]$$

## ◆ Magnetic (odd) multipoles

- M1, M3, ...  $M_\Lambda$  ( $\Lambda = 2J_0$ )
- example:  $^{87}\text{Sr}_{38}$  (neutron  $1g_{9/2}$ )

$$F_T^2(q) = \sum_{J=0}^{2J_0} F_{MJ}^2(q) = \frac{4\pi}{2J_0 + 1} \sum_{J=0}^{2J_0} \left| \langle \psi_A | \hat{T}_J^M(q) | \psi_A \rangle \right|^2$$

## ◆ Properties of multipoles

- MJ: peak at different  $q$  values
- M1 – M7: config. mixing
- M9: easy to isolate at high  $q$

# Valence proton and neutron radial distributions

- ◆ Simplification for “stretched” spin configurations:  $J_0 = l + \frac{1}{2}$

- Spin: highest one of all filled shells
- Multipole  $\Lambda = 2J_0$ : only intrinsic magnetization
- No conf. mixing from other nucleons
- Valid for **protons and neutrons**

$$F_{M\Lambda}(q) = C_{\Lambda} \alpha_{\Lambda} \mu \int_0^{\infty} R^2(r) j_{\Lambda-1}(qr) r^2 dr$$

- Example:  $^{87}\text{Sr}$

$$F_{M9}(q) \propto \int_0^{\infty} R^2(r) j_8(qr) r^2 dr$$

A clean way to measure both the **radius** and the **shape** of the valence nucleons

# Valence neutrons and protons : $^{87}\text{Sr}$ and $^{93}\text{Nb}$

Sick et al., PRL 38,1259 (1977).

Platchkov et al., Phys. Rev. C25, 2318 (1982).

## ■ Radii of the $1g_{9/2}$ orbit

Nucleus	Orbit	Valence radius (fm)		
		DDHFB	WS	WS + MEC
$^{87}\text{Sr}$	$1g_{9/2}^n$	4.832	4.756(72)	4.823(76) <b>neutron N = 49</b>
$^{93}\text{Nb}$	$1g_{9/2}^p$	4.931	4.897(58)	4.946(64) <b>proton Z = 41</b>

Proton and neutron  $1g_{9/2}$  orbits have the same shape  
 The neutron radius looks slightly **smaller** ( $2.5\% \pm 2\%$ ): no neutron halo

# Evidence for meson-exchange currents

## ◆ Meson exchange contributions

## ◆ => Electro-disintegration at threshold $d(e,e')pn$

- Deuteron binding energy: 2.2 MeV
- Threshold = cross section near 2.2 MeV ( $^1S_0$ )
- Deuteron:  $^3S_1$  (95%) and  $^3D_1$  (~5%) states
- Two transitions:  $^3S_1 \rightarrow ^1S_0$  and  $^3D_1 \rightarrow ^1S_0$

# Evidence for meson-exchange currents in the deuteron

## ◆ Electro-disintegration at threshold $d(e,e')pn$

Bernheim et al., PRL 46, 402 (1981)

Auffret et al., PRL 55, 1352 (1985)

Nucleon + meson theory provides good explanation of the data (up to  $q^2 = 28 \text{ fm}^{-2}$ )

# The neutron electric charge distribution?

- $e^- + d$  elastic cross section:

$$\frac{d\sigma}{d\Omega} = \sigma_M \left[ A(Q^2) + B(Q^2) \tan^2\left(\frac{\theta}{2}\right) \right]$$

- Form factors (deuteron spin = 1)

$$A(Q^2) = F_C^2(Q^2) + \frac{8}{9} \tau^2 F_Q^2(Q^2) + \frac{2}{3} \tau F_M^2(Q^2)$$

- Depends on:

- N-N potential
- Neutron form factor
- + Meson-exchange currents, Rel effects

Allows a model-dependent determination of the neutron electric form factor

# The neutron electric form factor, $G_E^n$

$G_{en}$  as determined from elastic  
electron-deuteron scattering

# The neutron electric form factor, $G_E^n$

$G_{en}$  as determined from elastic  
electron-deuteron scattering

$G_{en}$  from JLab and Mainz polarization data

# Three-nucleon system: $^3\text{He}$ and $^3\text{H}$

Juster et al., PRL 55, 461 (1985)

- ◆ Saclay tritium target (1985):
  - Sealed target,  $P = 3$  bars, cooled by liquid hydrogen at 20 K
  - Safety: 4 containers with many sensors, two independent computers
  - Activity: 10 kCi ( $3.7 \times 10^{14}$  Bq)

# Three-nucleon system – form factor measurements

Cavedon et al. PRL 49, 986 (1982)

Juster et al., PRL 55, 2261 (1985)

Amroun et al., PRL 69, 253 (1992)

Amroun et al., Nucl. Phys. A579, 596 (1994)

Charge form factors

Magnetic form factors

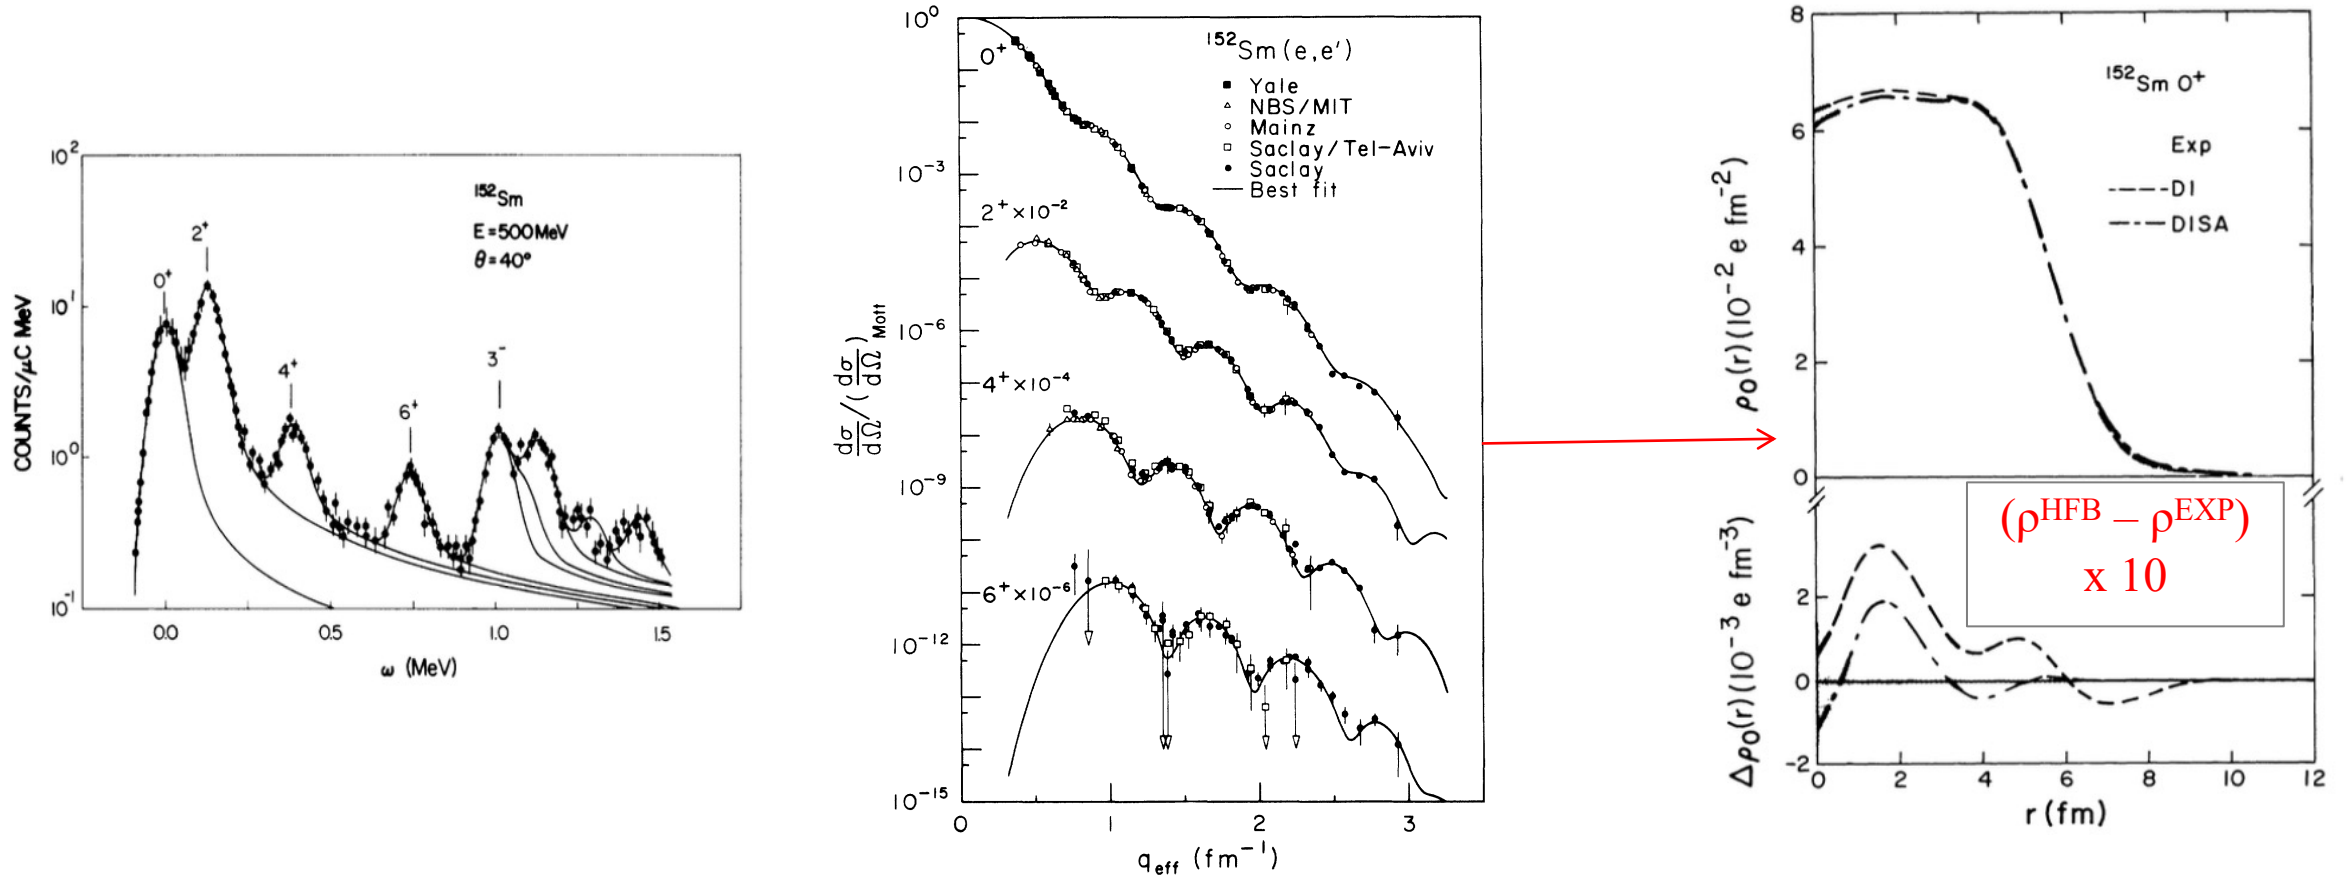

Meson-exchange currents are mandatory for a good description  
Three-body force has a minor effect

# Inelastic (e,e') scattering from $^{152}\text{Sm}$

- Transition charge densities for  $0^+$ ,  $2^+$ ,  $4^+$ ,  $6^+$

Phan et al., PR C38, 1173 (1988)

Comparison with a triaxial DD-HFB calculation

# Ground state and transitional charge densities of $^{152}\text{Sm}$

- Comparison with a triaxial mean-field HFB calculation  
(two versions of the effective Gogny force: D1 and D1SA)

Phan et al., PR C38, 1173 (1988)

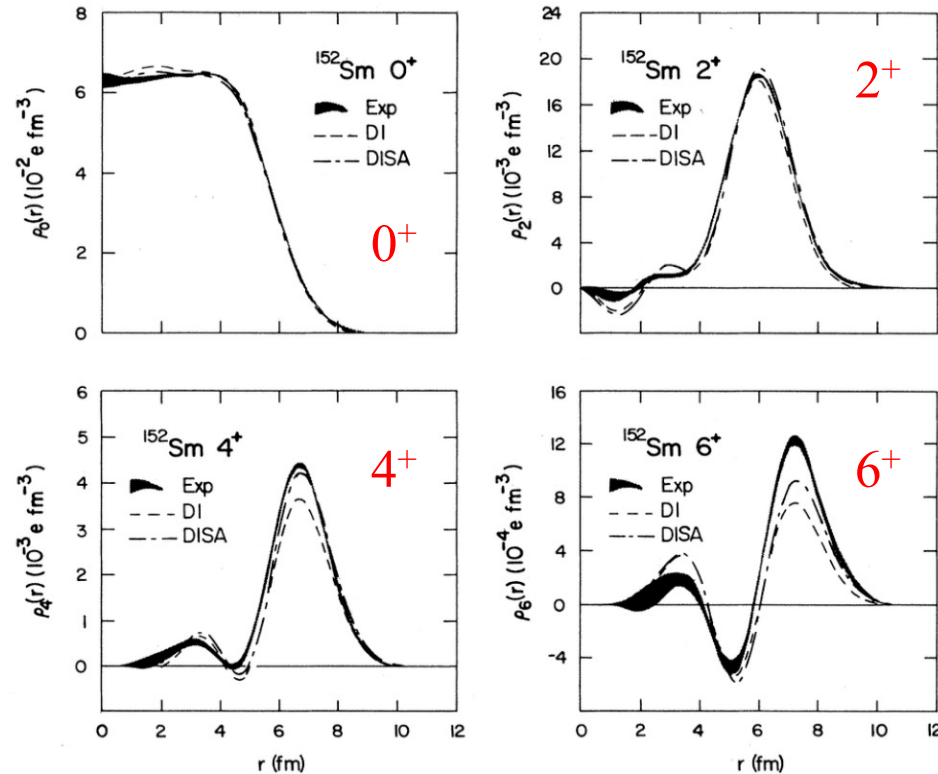

FIG. 8. The experimentally determined ground state and transition charge densities for the first four states of the ground state rotational band. Also shown are the theoretical predictions obtained using the D1 (---) and D1SA (-.-.-) effective interactions.

Potential energy surface of  $^{152}\text{Sm}$

The ground-state rotational band of  $^{152}\text{Sm}$  is well described by a HFB calculation

# A configuration mixing in $^{70,72,74,76}\text{Ge}$ isotopes?

- Two-nucleon transfer reactions: strange behavior around  $^{72-70}\text{Ge}$

$\Rightarrow (e,e')$ : Measure the transition charge densities of the first  $2^+$  states in the  $^{70,72,74,76}\text{Ge}$  isotopes

Electron scattering spectrum

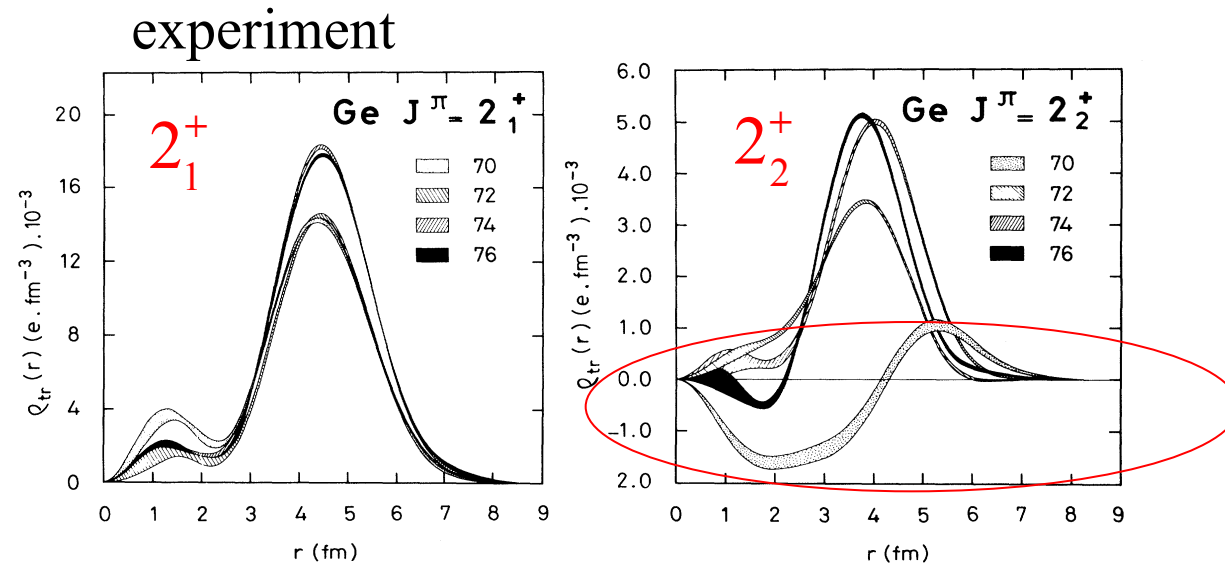

Why such a sudden change for  $^{70}\text{Ge}$  ?

Bazantay et al., PRL 54, 643 (1985)

# Configuration mixing in Ge isotopes – exp / th

- Interacting Boson Model: neutron and proton boson pairs
  - Combines single-particle and collective motions
  - Allows for configuration mixing

Evidence for the coexistence of two configurations; Agreement with IBM-2, only for different configurations in  $^{68,70}\text{Ge}$  vs  $^{72,74,76}\text{Ge}$

FIG. 3. Comparison between the predicted (thin line) and experimental (thick line) transition densities.

# Nice atmosphere...

# “Quasi-elastic” electron scattering

## ■ Quasi-elastic peak

$$\frac{d\sigma}{d\Omega dE} = \frac{4\pi}{M} \sigma_{Mott} \eta^{-1} \left[ \frac{q_\mu^2}{q^2} R_L(q, \omega) + \left( \frac{1}{2} \frac{q_\mu^2}{q^2} + \tan^2 \frac{\theta}{2} \right) \frac{q_\mu^2}{q^2} R_T(q, \omega) \right]$$

response functions:  $R_L, R_T$

## ■ Motivations

- scattering from quasi-“free” nucleons inside the nucleus
- probe the nucleon momentum distribution

Are nucleon properties modified in nuclear medium?

## ■ Coulomb Sum Rule

Meziani et al., PRL 52, 2130 (1984).

Meziani et al., PRL 54, 1223 (1985).

Marchand et al., PL 153B, 29 (1985)

$$S_L(q) = \frac{1}{Z} \int_{0+}^{\infty} \frac{R_L(q, \omega)}{\tilde{G}_E^2} d\omega$$

Nuclear matter effect: significant quenching (up to 30%)

# Coincidence experiments (e,e'p)

## ■ Kinematics - coincidence experiment:

- initial proton momentum
- proton removal energy

$$\vec{p} = -\vec{p}_B = \vec{e}' + \vec{p}' - \vec{e}$$

$$E = e - e' - T' - p^2 / 2M_{A-1}$$

$$\sigma(e, e' p) = \frac{d^6\sigma}{de' d\Omega_e dp' d\Omega_{p'}} = K \left( \frac{d\sigma}{d\Omega} \right)_p S(\vec{p}, E)$$

## ■ Information on:

- nuclear spectral function : momentum and energy distributions
- probe individual shells; access also to deeply-bound states

# Examples of (e,e'p) experiments

Mougey et al., Nucl. Phys. A262,461 (1976).

Access to: single-particle energy and momentum distributions,  
occupation probabilities, bound nucleon properties

# Bound proton form factor measurements

- Are nucleon properties modified in the nuclear medium?

Reffay et al., PRL. 60,776 (1988).

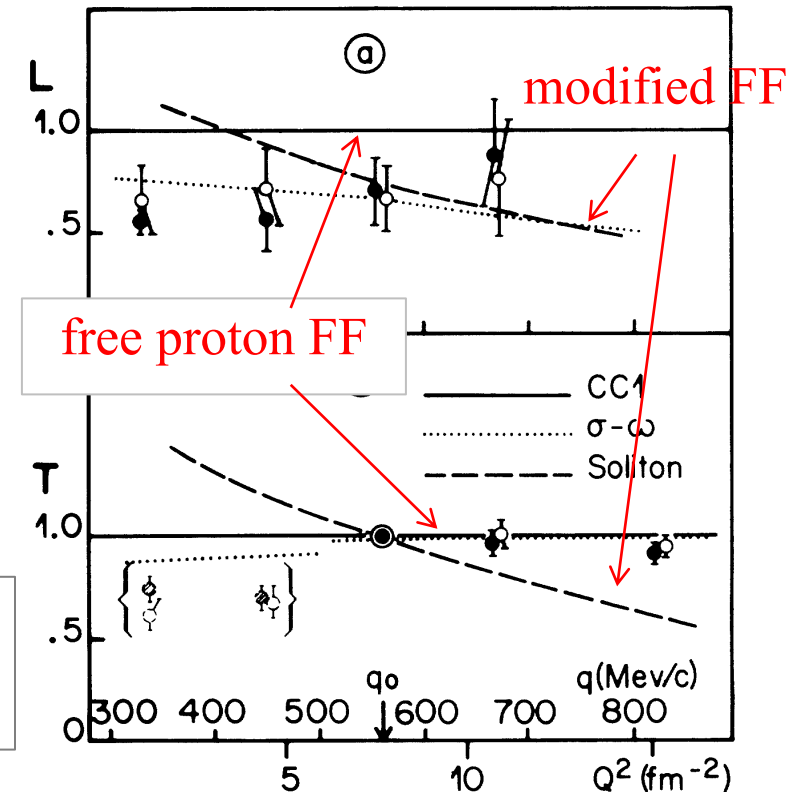

- in PWIA:

$$\sigma(e, e' p) = \frac{d^6\sigma}{de' d\Omega_e dp' d\Omega_{p'}} = K \left( \frac{d\sigma}{d\Omega} \right)_p S(\vec{p}, E)$$

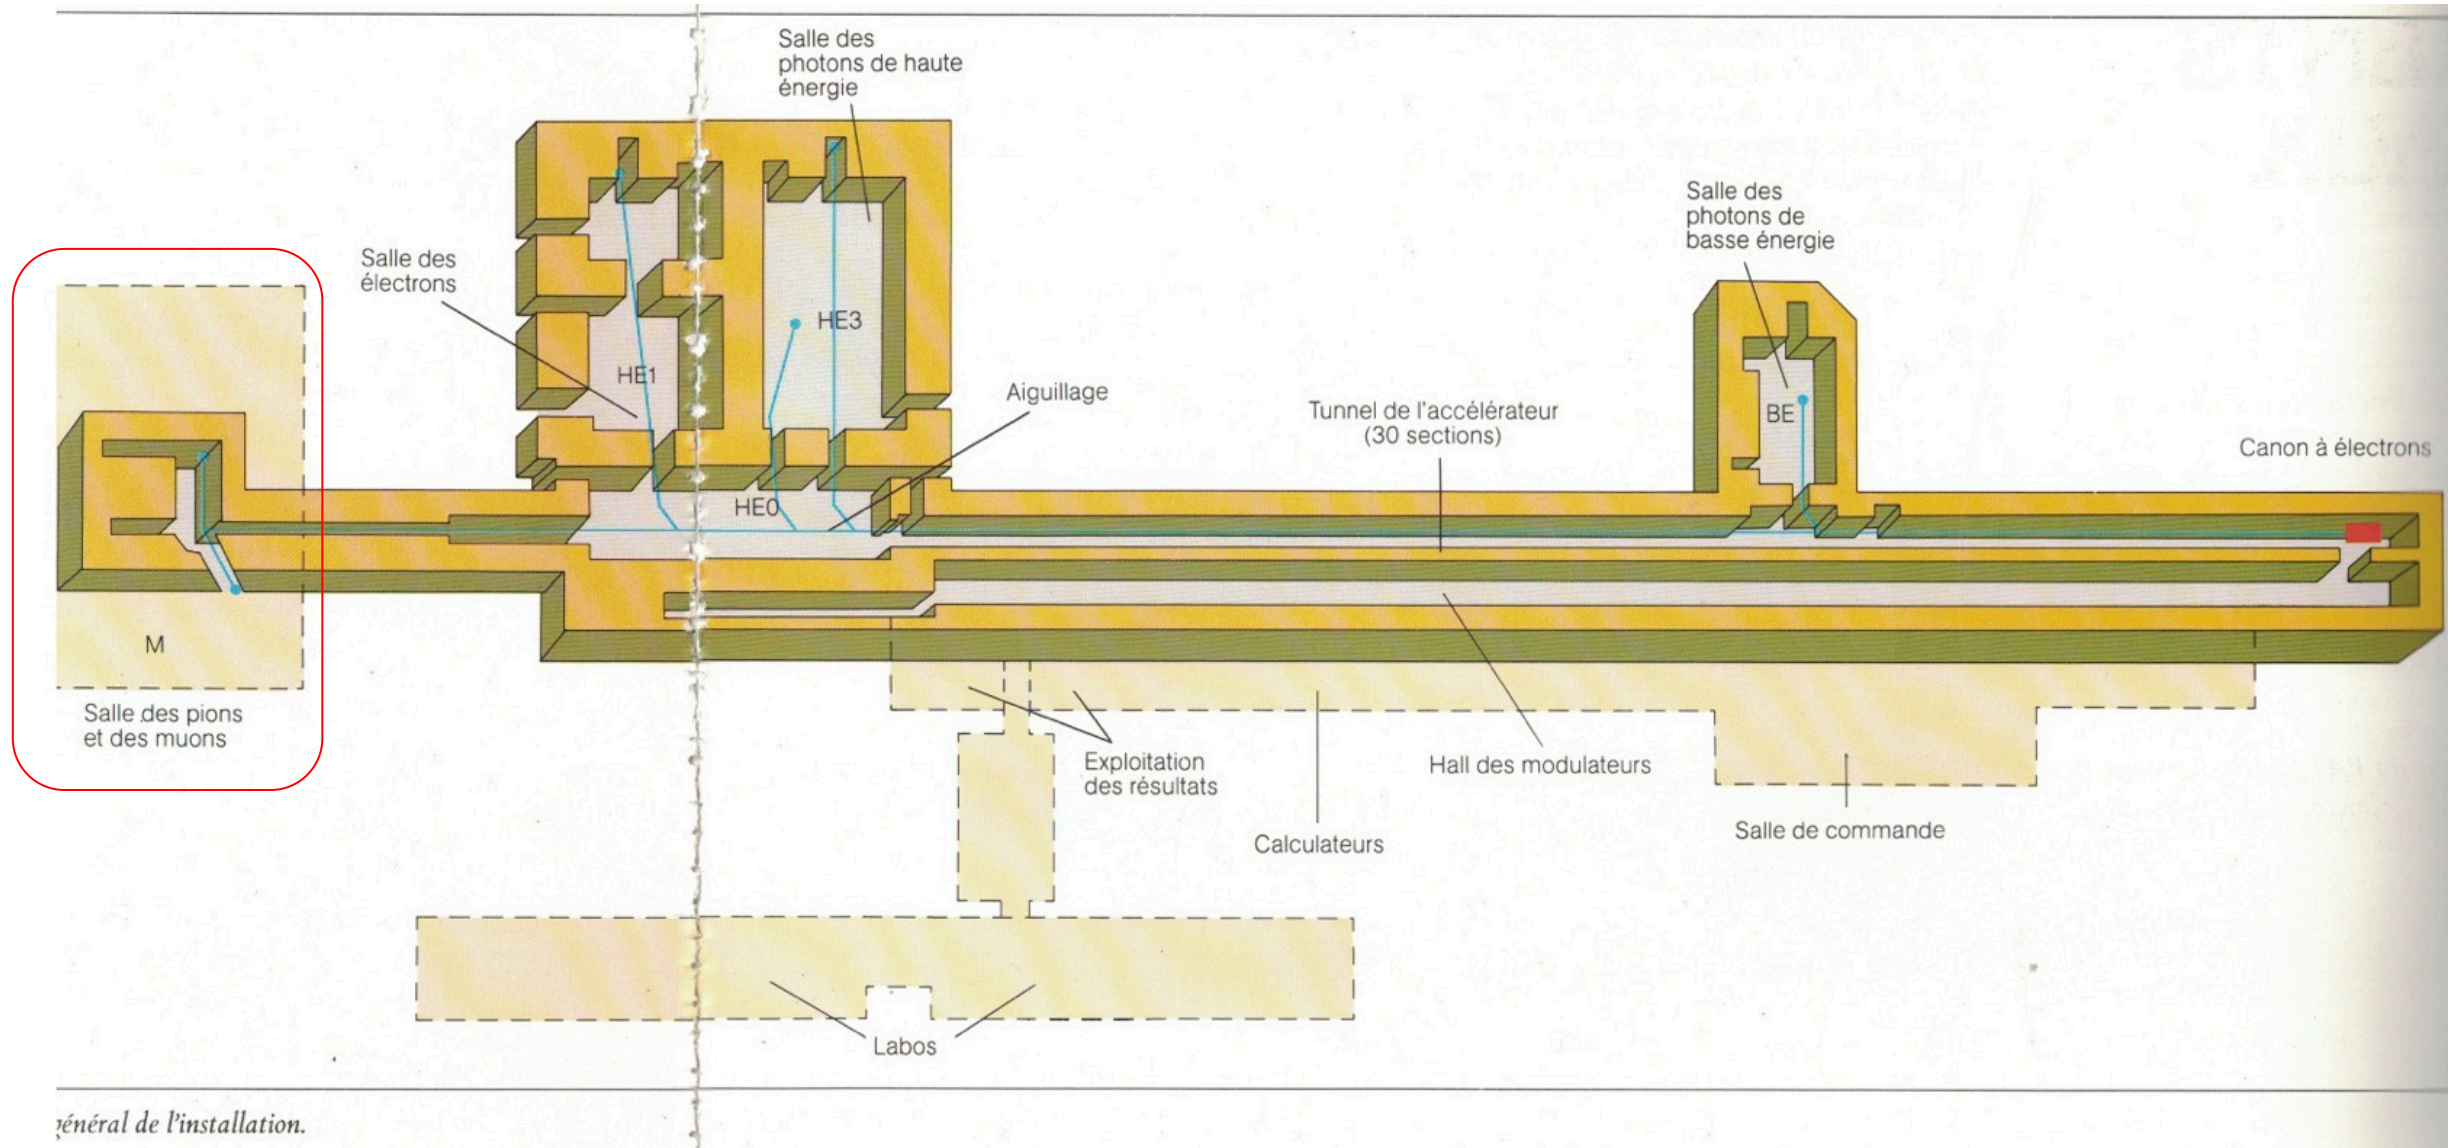

- Goal:

- study bound  $\sigma_{ep}$  q-dependence
- separate L and T contributions
- compare to DWBA calculations

No modification of the bound proton FF  
 L-response quenching  $R \sim 65\%$

# Overview of the laboratory (top view)

# SM basic parameters: $\mu$ lifetime, capture rate and weak ps coupling

## ◆ Muon lifetime measurements

- Stop the muons in a ultrapure "protium" target
- Physics results (errors of  $\sim 3 \cdot 10^{-5}$ )

$$\tau_{\mu^-} = 2194.903 \pm 0.066 \text{ ns}$$

$$\tau_{\mu^+} = 2197.148 \pm 0.066 \text{ ns}$$

Bardin et al., Nucl.Phys. A352 (1981) 365.

## ◆ Muon capture rate ( $\mu^- + p \rightarrow n + \nu_\mu$ )

- Related to the EW coupling constants  $g_A$ ,  $g_p$
- => Determine the ps coupling constant  $g_p$ :

- Saclay 1981:  $g_p = 8.70 \pm 1.90$

Bardin et al., Phys.Lett.104B (1981) 320.

Kammel, ARNPS 60 (2010).

# From ALS to e – RI collisions (eRIB) ?

---

- Electron machine
  - Beam energy: between 100 and ~500 MeV
  - Electron currents:  $\gg 100$  mA
  - Duty cycle:  $>1\%$  OK; coincidence: 100%
  - Luminosity: higher  $\mathcal{L} \Rightarrow$  larger  $q$ , access to more processes...
- Detection system
  - Resolution: 100 keV or better
  - Angular range: high enough ( $25^\circ - 155^\circ$ )
  - Background : low bgnd is mandatory (good shielding)
- Coincidence experiments?
  - Large energy and momentum acceptances
  - Good energy and momentum resolutions

# From ALS to e – RI collisions (eRIB) ?

## ■ eRIB project in France

- Radioactive nuclei:  $\sim 10^8/\text{s}$
- Beam energy: between 100 and  $\sim 500$  MeV
- Electron currents:  $\gg 100$  mA (synchrotron ? microtron + storage ring?)
- Luminosity: higher  $\mathcal{L} \Rightarrow$  larger  $q$ , access to more processes...
- Resolution: 100 keV or better
- Angular range: large enough ( $25^\circ - 155^\circ$ ) to separate L and T
- Background : low, mandatory if low cross section measurements

- ◆ ALS (1969 – 1992): a world-class facility – produced a number of “textbook” results
  - Electron scattering on nucleon and heavy nuclei
    - Charge and magnetization densities, transition densities, deformation studies, sum rules
  - Coincidence (e,e’p) experiments
    - Limits of the independent-particle picture, spectral functions,
  - Photonuclear experiments
    - $(\gamma,p)$ ,  $(\gamma,\pi)$ ,  $(\gamma,p\pi)$ , etc...
  - Secondary beams
    - Pion studies, Muon lifetime and capture rates
- ◆ Future: eRIB ?
  - Similar studies on exotic nuclei...
