

Studying the Low-Z coast of the Island of Inversion: Exploring Two-Neutron Halos in $N = 20$ and $N = 28$ Isotones

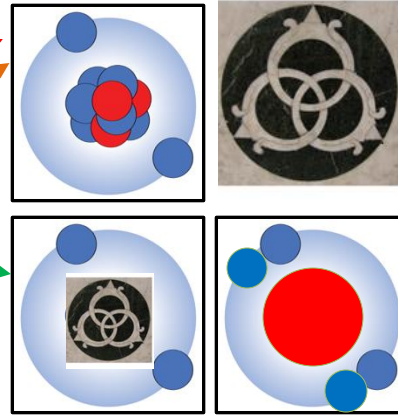

Jagjit Singh

jagjit.singh@manchester.ac.uk

04.12.2024 (11:30-12:15)

Introduction: 2n-halos (Borromean's)

Key features of Borromean nuclei :

- Corresponding subsystems are unbound.
- Low two nucleon *separation energies* ($s_{2n/p}$).
- Diffuse *matter density distribution*.
- Abnormally large *matter radius*.
- Large *reaction/interaction cross sections*.
- Strong *correlations* between the valence neutrons are key in binding two-neutron halos.
- Enhanced *low-lying E1 strength*.

Y. Kikuchi et al., PTEP 2016, 103D03 (2016).

T. Aumann, EPJA 55, 234 (2019).

Theoretically three-body (*core+n+n*) models describe reasonably well these features in *Borromean nuclei*.

Key inputs for these models are:

- Information on *core+n* low-lying spectrum
- Two-neutron separation energy.

Three-Body Structure Model- Hyperspherical framework

Three-body Hamiltonian is given by

$$H = T + \sum_{i=1}^2 V_{core+n_i} + V_{nn} + V_{3b}$$

$$V_{core+n_i} = \left(-V_0 + V_{ls} \vec{l} \cdot \vec{s} \frac{1}{r} \frac{d}{dr} \right) \frac{1}{1 + \exp\left(\frac{r-R}{a}\right)}, \quad V_{3b}(\rho) = v_{3b} e^{-(\rho/\rho_0)^2},$$

PHYSICAL REVIEW C **102**, 064627 (2020)

FIG. 1. Jacobi- T (left) and $-Y$ (right) coordinates for the ^{29}F nucleus described as $^{27}\text{F} + n + n$.

nn interaction- Gogny-Pires-Tourelil (GPT) interaction including central, spin-orbit and tensor terms.

D. Gogny, P. Pires, and R. D. Tourelil, PLB 32, 591 (1970).

The three-body force is modelled as a simple Gaussian potential, where $\rho = \sqrt{x^2 + y^2}$, is **hyper-radius** and $\rho_0 = 6$ fm and the strength v_{3b} is adjusted to recover s_{2n} .

We use the analytical transformed harmonic oscillator (THO) basis, obtained with LST, which changes Gaussian asymptotic behavior of the HO functions into a simple exponential. *J. Casal, M. Rodriguez-Gallardo, and J. M. Arias, Phys. Rev. C 88, 014327 (2013).*

The diagonalization of the three-body Hamiltonian requires the computation of the corresponding kinetic energy & potential matrix elements. **Spherical inert core approximation is used.**

Reaction cross-section within Glauber model

The reaction cross section for a projectile-target collision integrating the reaction probability with respect to the impact parameter b

$$\sigma_R = \int db (1 - |e^{i\chi(b)}|^2),$$

Phase shift function

$$e^{i\chi(b)} = \langle \Phi_0^P \Phi_0^T | \prod_{A_P} \prod_{A_T} [1 - \Gamma_{NN}(s_i^P - s_j^T + b)] | \Phi_0^P \Phi_0^T \rangle$$

Profile function
$$\Gamma_{NN}(b) = \frac{1 - i\alpha}{4\pi\beta} \sigma_{NN}^{\text{tot}} \exp\left(-\frac{b^2}{2\beta}\right)$$

PF describes interaction between projectile and target nucleons is expressed as

α, β : determined so as to reproduce the NN scattering

B. Abu-Ibrahim et al., PRC 77, 034607 (2008). W. Horiuchi et al., PRC 75, 044607 (2007).

Phase-shift function: Many-body operator

JC, JS, LF, WH and AV, PRC 102, 064227 (2020).

Tale of ^{29}F -III

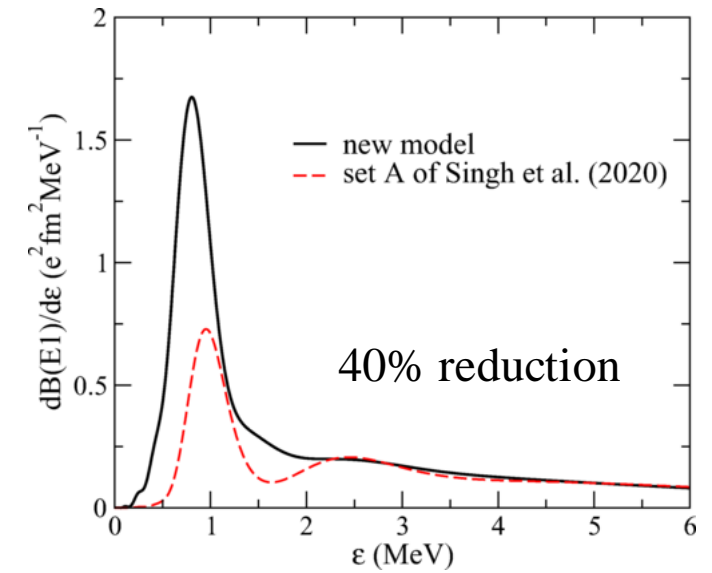

- Ground-state probability density (in fm^{-2}) of ^{29}F using the present three-body model, as a function of $r_x \equiv r_{\text{nn}}$ and $r_y \equiv r_{\text{c-nn}}$.
- The large mixing between the $(p_{3/2})^2$ and $(d_{3/2})^2$ components is responsible for the strong dineutron peak and plays a key role in the formation of the two-neutron halo

- Energies of the $0+$, $1-$, and $2+$ states of ^{29}F obtained with Pseudo state method.
- Interestingly, the same Hamiltonian produces a very weakly bound $2+$ state at $E \sim 0.1$ MeV. This energy is not quantitatively consistent with the experimental value, but given the simplicity of the model, the qualitative agreement is remarkable.

P. Doornenbal, et al., PRC 95, 041301(R) (2017).

$$B(E\lambda) = |\langle n_0 j_0 || \hat{O}_{E\lambda} || n j \rangle|^2.$$

- $B(E1)$ distribution obtained in the Inverted scenario (solid black line) compared with the results using the potential set A of Ref. [1] (dashed red line), which corresponds to a standard shell-model order.
- $B(E1)$ distribution is highly sensitive to the ground-state radius and configuration mixing.

Two-body (core+n) models for ^{39}Mg and ^{38}Na

[K. Fosse, et. al., PHYSICAL REVIEW C 94, 054302 \(2016\).](#)

Unbound ground state of ^{39}Mg is predicted to be either a $J^\pi = 7/2^-$ or $3/2^-$ state.

A narrow $J^\pi = 7/2^-$ or $3/2^-$ ground-state candidate exhibits a resonant structure at 129 KeV.

As we do not have either theoretical or experimental predictions and data for ^{38}Na , we use the same *core+n* potential parameters as for ^{39}Mg . The only changes are $R_c=1.25A^{1/3}$ and the spin-orbit strength.

Configuration mixing and matter radii for ^{40}Mg and ^{39}Na

^{40}Mg (s_{2n}) = 0.670 (0.710) MeV

M. Wang, *et. al.*, Chinese Physics C **45** (3), 030003 (2021).

Matter radius of core ^{38}Mg =3.60 fm

S. Watanabe, *et. al.*, PRC **89**, 044610 (2014).

^{39}Na (s_{2n}) = unbound

M. Wang, *et. al.*, Chinese Physics C **45** (3), 030003 (2021).

^{39}Na (s_{2n}) = bound (Contradicts AME)

D. S. Ahn *et al.*, PRL **129**, 212502 (2022).

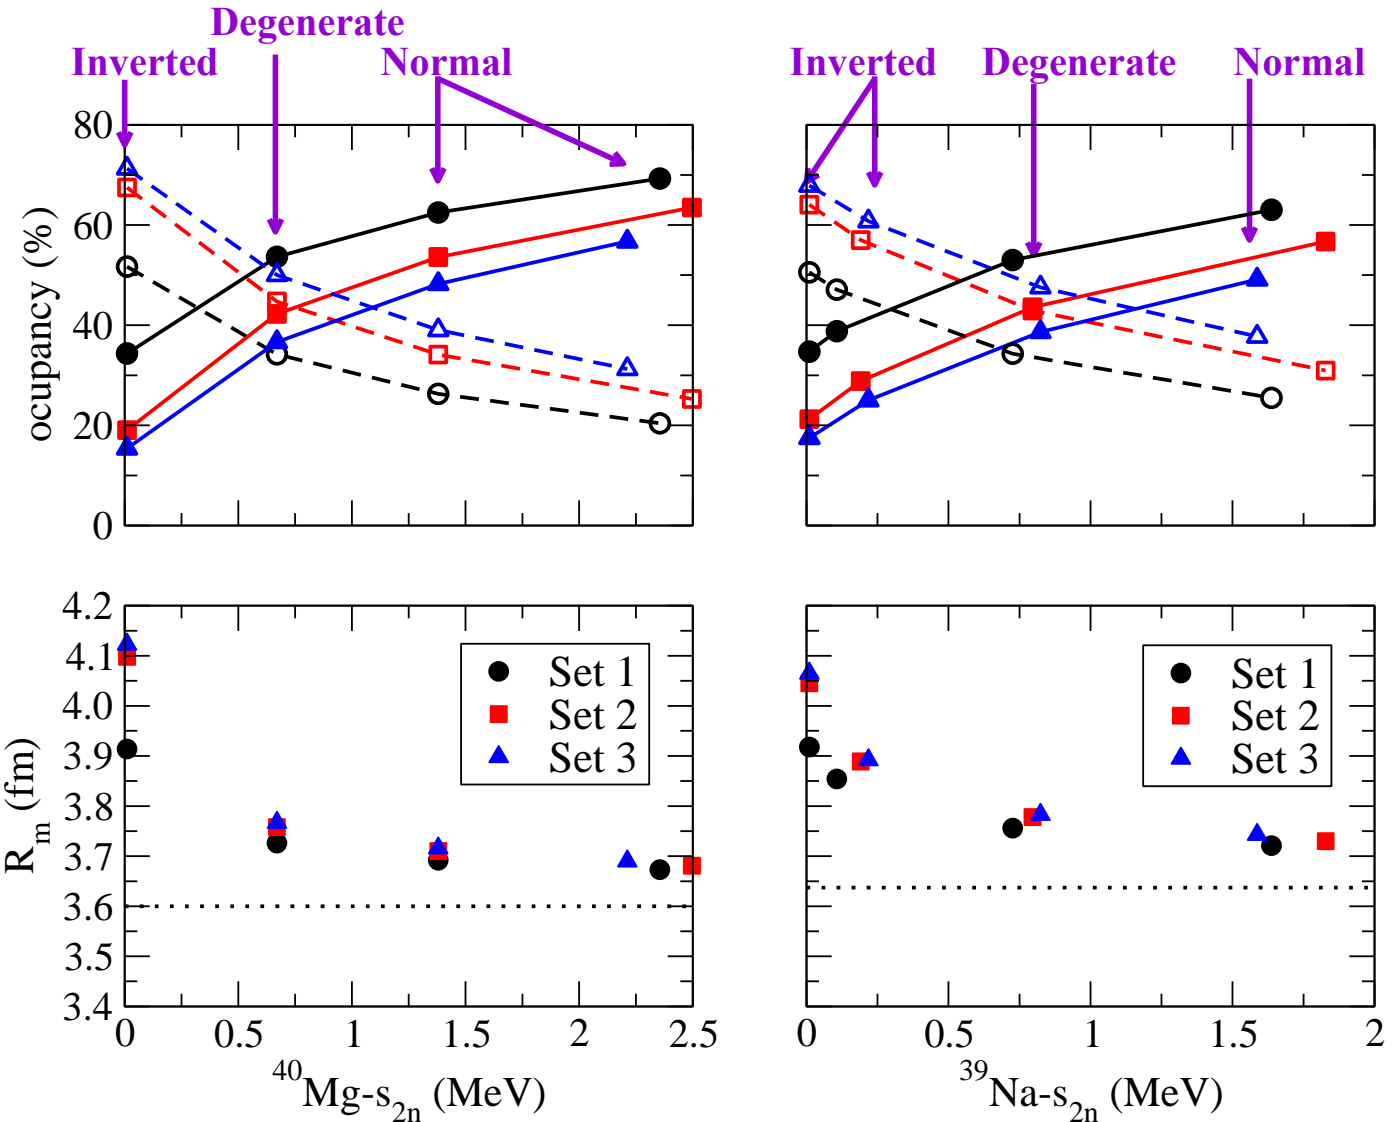

Matter radius of core ^{37}Na =3.64 fm

L. Geng, *et. al.*, NPA **730**, 80 (2004).

Our predictions for s_{2n} of ^{39}Na

0.010-0.824 (1.828) MeV

The larger change in R_m *w.r.t* core involves wave function which contains significant $(p_{3/2})^2$ (dotted lines) weight, pointing toward the necessity of intruder configurations to sustain halo formation. $(f_{7/2})^2$ (solid lines)

Matter radii for ^{40}Mg and ^{39}Na

- Dotted black lines in the figure correspond to the weighted fit of the experimental data points with the standard $R_0 A^{1/3}$ formula.
- The radii of ^{40}Mg and ^{39}Na are higher than the standard fitted value.
- This observation implies a likely two-neutron halo structure in the ground state of ^{40}Mg and ^{39}Na , and the corresponding melting of the traditional $N = 28$ shell gap is due to the intrusion of the $p_{3/2}$ orbital.

- Ozawa *et al.*, Nuclear Physics A **691** (3), 599 (2001).
- Kanungo *et al.*, Phys. Rev. C **83**, 021302 (2011).
- Takechi *et al.*, Phys. Rev. C **90**, 061305(R) (2014).
- JS, J. Casal *et al.*, Physics Letters B **853**, 138694 (2024).

Reaction cross-sections for ^{40}Mg and ^{39}Na : within Glauber reaction theory

- Experimentally, a very obvious way to determine whether a nucleus is a halo nucleus, is to look for an enhanced reaction cross section. Thus, we examine the total reaction cross section by employing the conventional Glauber theory. *B. Abu-Ibrahim et al., PRC 77, 034607 (2008). W. Horiuchi et al., PRC 75, 044607 (2007).*
- Using this prescription, we predict the σ_R for ^{40}Mg and ^{39}Na at different incident energies. The predicted values of σ_R for ^{40}Mg and ^{39}Na show significant enhancement with respect to the observed σ_R in the lower-A isotopes for both choices of energy.

Thus, our results provide a clear signal of the 2n-halo structure formation in ^{40}Mg and ^{39}Na and hence melting of the $N = 28$ shell closure.

- Ozawa et al., Nuclear Physics A 691 (3), 599 (2001).*
- Kanungo et al., Phys. Rev. C 83, 021302 (2011).*
- Takechi et al., Phys. Rev. C 90, 061305(R) (2014).*
- JS, J. Casal et al., Physics Letters B 853, 138694 (2024).*

Summary:

- We started with studying melting of N=20 (*JS, JC, WH, LF, and AV, PRC 101, 024310 (2020)*) for ^{29}F . Our results/predictions got boost with new measurements (*S. Bagchi et al., PRL 124, 222504 (2020)* and *A. Revel et al., PRL 124, 152502 (2020)*). We updated our calculations with precise calculations along with detailed analysis of electric-dipole response and reaction calculations (*LF, JC, WH, JS, and AV, Commun. Phys. 3, 132 (2020)* and *JC, JS, LF, WH, and AV, PRC 102, 064627 (2020)*).
- Motivated by melting N=20 ends up in formation of Borromean in ^{29}F , by using same prescription we reported first three body results for ^{39}Na and ^{40}Mg lying on low-Z side of N=28. (*JS, J. Casal et al., Physics Letters B 853, 138694 (2024)*).
- Our results calls for new precise mass measurements for s_{2n} of three-body systems and the low-lying continuum spectrum of two-body subsystems to better constrain the theoretical models.
- The disappearance of the conventional N=28 shell gap and emergence of the halo leads to significant occupancy of intruder $p_{3/2}$ orbit in the ground state of ^{39}Na and ^{40}Mg . Nevertheless, it is imperative to verify this conclusion through experimental measurements of interaction cross sections and transfer or knock out data to probe partial-wave content.

Future Perspectives:

- It is interesting to see how our predictions are affected with inclusion of core deformation effects.
